THE researches on which Dr. v. Descatello and Dr. Krjukoff's work is based were made in the medical clinic of Innsbruck during 1909–10. The chief fixing and staining method used was that of Pappenheim, who combined the Jenner stain, or, as it is called in Germany, the May-Grünwald stain, with the Giemsa stain. The fresh film is fixed for one minute with the Jenner stain, then stained for three minutes with the same stain diluted with an equal volume of distilled water, and after being washed in distilled water it is stained for 15 minutes in Giemsa's stain, washed, dried, and mounted in acid-free balsam. This method reveals in all nuclei of nucleated blood cells a fine dense network of fibrils (which the authors call the "primitive fibres") of uniform size, most being of a red-violet tinge. The protoplasm of all nucleated blood cells, with the exception of erythroblasts, also contains a network of fibrils, some of which are thicker than the nuclear fibres, and they stain in various nuances, and some of the fibres are in direct continuity with the fibres of the nucleus. Very careful descriptions are given of the various forms of cells found in blood, as revealed by the methods used by the authors, and 102 separate coloured figures are given on the eight plates. Most of the figures are drawings, some of them magnified 1000 times, from two cases which were observed with great care, one of carcinoma of the prostate with secondary metastasis in the bones and severe anæmia, the other a case of acute myelogenic leukæmia. The results are interesting, both to physiologists and pathologists. The authors conclude that to regard the nucleus as a vesicle with a membrane is not a correct view; rather are the body of the cell and the nucleus to be regarded as a complex network of fibres which permeates the whole mass of the cell. Each nucleus possesses the power and capacity by rearranging its fibres to make a curved or jointed polymorphonuclear form or convolution. Nucleus and protoplasm are not two sharply defined anatomical and functional parts of a cell; they are in the most intimate connexion, and fibres from the nucleus may pass into the

body of the cell. The granules seen in the protoplasm are not secretory products of the cell body, as surmised by Ehrlich, but are to be regarded as changed segments of the karyogenetic protoplasmic fibres. Very interesting are the observations on the blood plates, which are not all of one variety, and are chiefly derived from the cytoplasm of neutrophile leucocytes, though other cells give rise to them, and they differ according to their source. The book is a piece of painstaking, laborious work.

Dr. Pappenheim's opuscule is a reprint from Carl Neuberg's "Handbuch der Ausscheidungen und Körperflüssigkeiten" (1911), and is written by one who is a recognised authority on the subject. It deals with the microscopic examination of blood, normal and abnormal, hæmocytometry and hæmoglobinometry. According to the author, the one method for fixing and colouring blood films is the combined May-Giemsa (Jenner) colouration, as invented by himself. There are no illustrations. It is a commendable and useful little brochure.

The Errors of Accommodation and Refraction of the Eye and Their Treatment. A Handbook for Students. By ERNEST CLARKE. London: Baillière, Tindall, and Cox. 1911. Pp. 228. Price 5*s.* net.

WHEN a book has reached its third edition it must be concluded that it fulfils the demands of a considerable body of readers. There are several good books on errors of refraction and cognate disabilities of the eye, but Mr. Ernest Clarke's book can well hold its own amongst them. The optical side of ophthalmology has proved a terrible stumbling-block in the path of the medical student and practitioner, and they are ever ready to hail some expanded and, so far as may be, simplified exposition of the subject. Mr. Clarke, by the free use of diagrams and the avoidance of formulæ, has given a lucid account of the dioptrics of the eye and the optical errors which so frequently affect it. His teaching as to the diagnosis and correction of such errors is satisfactory and trustworthy. We do not agree with his strong advocacy of the ophthalmometer as a clinical instrument, but that is a detail of relatively small importance. The book has been improved in successive editions and minor blemishes will doubtless be removed in the editions yet to come.

---

1 *Text-book of Physiology for Medical Students and Physicians* By WILLIAM H. HOWELL, Ph.D., M.D., Sc.D., LL.D., Professor of Physiology in the Johns Hopkins University, Baltimore. Fourth edition, thoroughly revised. London: W. B. Saunders Company. 1911. Pp. 1018. Price 18*s.* net.

THE issue of the fourth edition of Professor Howell's "Text-book of Physiology"—a book which is now recognised as a standard and trustworthy work on both sides of the Atlantic—will be welcomed. The last edition was reprinted in January and July, 1910. The ever-widening boundaries of physiology make it more and more difficult for any one individual to gain a familiar, far less a first-hand, knowledge, not only of its by-ways, but of some of its main routes. This work is not an arid statement of facts, dry and dogmatic in form; on the contrary, it is characterised both by suggestiveness and a vigorous vitality, while it forms a compact epitome of the salient and pregnant facts, and their application in practical medicine, such as can be given only in a work written by a single author who has proved himself both a successful teacher and experimenter, and who has a wide and comprehensive knowledge of physiological literature in all its branches.

Professor Howell's text-book is well abreast of the ever-advancing tide of physiological knowledge. The author has succeeded in embodying in his text the outcome of the two principles which guided him in writing this book—viz., to set forth the presentation of facts and theories in simple and lucid form, and to select the material with judicious limitations. The general arrangement in previous editions is adhered to. The schema displaying the innervation of voluntary skeletal muscles still stands in its simplicity, showing only two neurons from cerebrum to muscle. The pyramidal tract has now been demonstrated not to terminate in the cord, as figured in this schema. The sections on muscle, nerve, and central nervous system are added to here and there, and, as in previous editions, a special chapter is devoted to the physiology of sleep, a subject too frequently dealt with in a cursory manner or even omitted altogether. The views of Head and Rivers on protopathic, epicritic, and deep sensibility are set forth pretty fully, but the author does not submit the results to detailed criticism. There is little charge in the description of the senses of vision and hearing. An excellent dissection shows the position of the semicircular canals in the pigeon and the relations of their ampullary ends. The whole question of the functions of these canals is dealt with very fully; in fact, the exposition is one of the best and most concise in any text-book of physiology intended for the use of students. The introduction of the dates of the successive researches on which each experimenter's view is founded enables the reader to see how recent our real knowledge actually is—e.g., Flourens (1824), Goltz (1870). For the present, "while the endolymph theory may be criticised easily, no other equally satisfactory theory has been suggested to take its place." This statement may be taken as an example of the author's fairness in dealing with a complex subject after setting forth the main facts. It is satisfactory to find that such a question as "reaction of the blood" is dealt with in the light of the latest advances in physical chemistry, and that the blue reaction of litmus to blood plasma is no longer the basis as a true indication of alkalinity.

Physiology links itself up with the question of immunity and the wonderful protective adaptation of the body towards the invasion of foreign cells. The author's account of this and allied matters forms an excellent introduction to the more elaborate treatment of this subject, which the student will learn from the pathologist and the clinician later. Here and there histological figures, some coloured, are introduced, but leucocytes in all their varieties are described without the aid of diagrams—coloured or otherwise. Reference is made, however, to Pappenheim's Atlas, an atlas which the average student is not likely to consult. On p. 447, when mentioning certain facts regarding coagulation of the blood, it would have been instructive to insert after each of the names mentioned the dates of their discoveries. The presentment of the whole question of coagulation of the blood, however, is both excellent and suggestive.

The importance of a knowledge of venous and capillary pressures becomes daily more important. This subject is dealt with more fully than in most text-books, and so also is what is called the "hydrostatic effect," which enables the author to set forth the important work done by Leonard Hill and his pupils. Full effect also is given to the recent work of Mackenzie on the heart and pulse. Having regard to what is called "heart block" from the clinician's point of view in relation to the auriculo ventricular bundle, there is a very good account of the arrangement of the heart fibres—even to the recent description by Mall—nor are the observations of Keith and Flack omitted. When discussing the myogenic *versus* the neurogenic theory of the heart beat the author puts on one page (556) in small print a succinct account of the "dividing line between the ancient and the modern views of the heart beat as is found in the work of William

Harvey (1628)." On the same page (556) we find that Remak (Robert) discovered intrinsic nerve ganglia in the heart in 1844, while in large text on p. 555 the date is given as 1848—a small slip which has escaped revision.

The tracings of blood pressure and respiratory movements are very good. An electrovagogram from Einthoven is given to show the electrical changes in the different fibres of the vagus caused by respirations and the heart beats, but there are no X ray photographs to show the movements of the contents of the intestinal tract. The chapter on the ductless glands and internal secretions is pithy, compact, and excellent throughout. A relatively long and critical account is given of the action of alcohol. The views of Darwin, de Vries, and Mendel are set forth in the interesting chapter on heredity, while the important subjects of growth and senescence are not forgotten.

The author is to be congratulated on the comprehensiveness and thoroughness of his work—a work which should be read by every advanced student of physiology, as well as by the practitioner.

The Deaf Child: A Manual for Teachers and Scholars. By JAMES KERR LOVE, M.D. Glasg., Aural Surgeon, Glasgow Royal Infirmary, Aurist to Glasgow Institution for Education of the Deaf and Dumb, &c. With 10 illustrations. London: Simpkin, Marshall, Hamilton, Kent, and Co; Bristol: John Wright and Son, Limited. 1911. Pp. 192. Price 4*s.* 6*d.* net.

Dr. Kerr Love opens with a careful *résumé* of the various work which has been done towards the education of the deaf. He next proceeds to argue as to the value and the necessity for the proper classification of deaf children, dividing them as fit for ordinary schools, fit for front row of ordinary schools, the hard of hearing, fit for deaf schools, and the mentally defective. He concludes his introductory chapter by a short dissertation on the advisability or otherwise of the deaf child leaving his home and indicates when he should begin to be instructed. After a short and popular exposition of the causes of deafness, with a few words on the physiology of hearing, we come to a chapter of great interest on the operation of the language centres in normal and abnormal children. Dr. Kerr Love shows the various ways in which the working of thought, hearing, and speech is carried on in normal and abnormal children, and here makes full use of the cases of Helen Keller and Laura Bridgeman.

There is a very interesting statement made on p. 64 with regard to the effect of adenoids in children. Only 12·8 per cent. out of 3500 Swedish children examined had well-marked adenoids, though another return shows that 16 per cent. had sufficient adenoids to demand their removal. This would seem to be a low proportion, compared with that existing certainly in England at the present time. Again, on p. 65, Dr. Kerr Love makes a most pertinent statement when he says that the only test of hearing of any practical value in the school child is the human voice, and that the most uniform method of applying the test is by whispered speech. He states later that the average hearing distance for whispered speech in a noiseless room is about 25 yards, and he says that a child who is able to hear whispered speech at 5 yards only may be called slightly hard of hearing; but as sound decreases with the square of the distance, one would think that the 5 yards might be considerably increased for the slightly hard of hearing. However, that is not of any great moment, and does not in the least diminish the value of the author's observations. Continuing this subject, the propriety of determining what residual hearing there is in each subject is discussed, and a chart of a great many different children is given, showing the various islands of active nerve tissue remaining in their cochleæ.

A chapter is devoted to the various conditions of education of the deaf, and gives fairly complete records of the different schools and the methods employed there, both in the British Isles and abroad. Amongst the interesting facts mentioned is that the first public school in Great Britain for the teaching of deaf children was founded in 1792 in the Old Kent-road, though it was preceded by just 32 years by that of the Abbé de l'Epée in Paris. The next chapter is concerned with the methods of education, and very fully deals with the various aspects, the greater need for more schools, and the better methods, or combination of methods, that should be employed. The treatment of deaf children forms the subject matter of the seventh chapter, and is divided into the surgical and the educational treatment. The eighth chapter is on lip-reading, and this is followed by an appendix on the capacity of the deaf for higher education, consisting largely of letters from various deaf people who are holding useful and honourable situations in life. A second appendix deals with the condition of the eyes of a deaf child, by Dr. H. Wright Thomson, and it appears from this report that the visual condition of children in the deaf-and-dumb schools is worse than that which obtains in any board school. Appendix 3 is a short chapter on stammering and cleft palate.

We can hardly speak in too high terms of this book. It is one which has been written largely for the teacher of deaf mutes and deaf children, and for school medical officers, but it will appeal not only to them but to the entire medical profession; and over and above them to all those who are interested in the welfare of these unfortunate beings who have lost the power of hearing in early childhood, and who, without a really careful training, are precluded from occupying any useful sphere in life, but who, if properly taught, are fully capable often of great intellectual development. It is a book which should be in the hands of all teachers of the deaf and of those interested in the question, whether from a social, educational, or charitable aspect.

Sociology Applied to Practical Politics. By JOHN BEATTIE CROZIER, Hon. LL.D., Author of "Civilisation and Progress," &c. London: Longmans, Green, and Co. 1911. Pp. 320. Price 9*s.* net.

Dr. Beattie Crozier, who was at one time in practice as a physician, has devoted many years to the study of sociology, and has made important contributions to its literature. His scientific and medical training gives him a point of view rarely possessed by purely political writers, while his connexion with Canada tends to give a breadth of idea scarcely attainable by writers whose horizon is bounded by the limits of England.

The volume comprises reprints of articles from the *Fortnightly Review*, the *Daily Mail*, and the *New Age*, ranging in date from 1902 to 1908, and embracing subjects falling chiefly under two heads—Socialism and Fiscal Policy. Some of the articles on Socialism are direct criticisms of Karl Marx, the Fabian Society, and Mr. H. G. Wells. The depth of these articles varies perhaps with the depths of the persons criticised. A writer might sport with Mr. Wells, possibly banter the Fabians, but could anyone be light-hearted with Karl Marx? It seems hardly possible, but Dr. Crozier does his best, with very readable results. If there are fallacies in the criticism, there are plenty in "Das Kapital," and perhaps the most glaring is the Socialist notion that manual labour is the only labour performed on the earth and the only effort deserving of payment or reward. If we follow the interpretation of advanced Socialists to its logical conclusions, within the limits of our profession the surgeon would be entitled to fees because he is a manual labourer; the physician could demand nothing

but bare honours. Neither the labour and time spent in training the eye and hand of the surgeon nor the logical faculties of the physician have any recognition as "work."

"Suggestions for a New Political Party" is the title of a somewhat diffuse chapter of thoughts on Party politics, as the game is now played in England. There is much that is refreshing in these pages to men who have not been brought up to believe that politicians have a monopoly of intelligence, learning, and integrity, but the subject is too vague for definite instruction. A chapter on "Taxation Schemes and their Values," reprinted from the *Financial Review of Reviews* (April, 1909), is much more concise, and gives a valuable sketch of the theories of land taxers headed by Henry George, and those of the extinguishers of capital—Mr. Sidney Webb and Mr. Bernard Shaw on the one hand, and on the other of the Independent Labour Party, "all of them the pale ex-sanguined ghosts of Karl Marx and the army of continental Socialists." Finally, Dr. Crozier becomes too technical for ordinary palates in the consideration of fiscal policy and "the English banking system," though even here the untechnical person finds valuable clues to modern lines of thought on these matters.

Diseases of the Skin, an Outline of the Principles and Practice of Dermatology. By Sir MALCOLM MORRIS, K.C.V.O., Surgeon to the Skin Department of the Seamen's Hospital, Greenwich. Fifth edition, revised by the Author, with the assistance of S. ERNEST DORE, M.D. Cantab., M.R.C.P. Lond.; Assistant in the Skin Department of the Middlesex Hospital. With 10 coloured and 67 black and white plates. London: Cassell and Co., Limited. 1911. Pp. 762. Price 10*s.* 6*d.*

THE first edition of this work appeared 18 years ago, and the reception which it then met with and the issue of four subsequent editions prove its value. We welcome this, the fifth, edition, for it will more than maintain the reputation of its predecessors. It contains in a fairly small volume a clear, exact, and indeed authoritative account of a branch of medical practice which is among the most difficult of all for the student to learn; and it is illustrated by a large number of excellent plates, several of them in colours, which give very good representations of the appearances presented by disease. The present edition has been brought fully up to date, and in this the author has had the assistance of Dr. Ernest Dore. No more useful treatise on cutaneous medicine has been published, and the student or practitioner who desires to acquire or improve his knowledge of this branch of medicine cannot do better than read this work.

Love and Marriage. By ELLEN KEY. Translated from the Swedish by ARTHUR G. CHATER. London and New York: G. P. Putnam's Sons. 1911. Pp. 399. Price 6*s.* net.

WE cannot quite understand whether this book is intended to be a scientific contribution to all-important questions relating to love and marriage, or merely an account, by a member thereof, of the views of a particular sect, referred to on p. 6 and elsewhere throughout the book, as "those who profess the faith of Life." The book contains a number of opinions and statements apparently quite unsupported by any evidence, and in places self-contradictory. Many of the chapters treat of generally received notions of morality and religion, as matters which the believers in "the faith of Life" consider utterly false and wrong. But there is nothing to show that the views are superior in ethical value to, rest on a firmer basis than, or would bring about better results than accepted ideas. The first seven chapters are somewhat disjointed disquisitions upon love, the right of motherhood, exemption from motherhood, and collective motherliness. They contain passage after passage of unsupported opinions, written (this may be due to bad translation) in a singularly involved and high-flown style. Apparently their purport is to lead up to the last two chapters, entitled respectively, "Free Divorce" and "A New Marriage Law." So far as we understand Miss Key's arguments, the conclusions of the first-named chapter seem to be: (1) Early marriages are the great remedy for immorality (p. 311); but (2) early marriages are often failures, as the choice is often unsuitable, and the individuals themselves change in the course of years (p. 312 *et seq.*); therefore (3) free divorce must accompany early marriages.

While everyone will allow that the present-day marriage law is not perfect, that the divorce laws are unjust, and that unhappy marriages are by far too common, we cannot think that the opinions expressed in this book, if carried into practice, would bring about a better or more desirable state of matters than exists at present.

Plastic and Cosmetic Surgery. By FREDERICK STRANGE KOLLE, M.D., Fellow of New York Academy of Medicine. With 1 coloured plate and 522 illustrations in the text. London and New York: D. Appleton and Co. 1911. Pp. 511. Price 21*s.* net.

THE value of cosmetic surgery is hardly sufficiently recognised by the medical profession, with the result that much of the work has fallen into the hands of unqualified practitioners and beauty specialists. It is deserving of more careful study, for slight malformations which appear unimportant to others are often the cause of the greatest annoyance to those who possess them. The work before us deals with almost the whole range of cosmetic surgery. The earlier chapters are concerned with the antiseptics to be used and the dressings and sutures to be employed. The most suitable anæsthetics for cosmetic work are also discussed, and for local anæsthesia the author prefers beta eucaine. The general principles are also laid down and skin-grafting is described. Then the several regions are considered in turn, the surgery of the eyelids being taken first. The surgery of the auricle of the ear follows, and the author describes how to remedy outstanding ears. Hare-lip is dealt with, but nothing is said of the surgery of cleft palate, though that surely belongs to plastic surgery. The author describes the employment of paraffin for the remedy of deformities, and a full account of rhinoplasty is also given. He concludes with such minor operations as the electrolysis of nævi and the removal of superfluous hairs. We cannot agree with the statement that it is ever necessary to use such a large current as one of 14 milliampères for the electrolysis of a hair.

We are pleased with this work; it should prove useful to those who wish to practise this branch of surgery.

The Technology of Bread-making. By WILLIAM JAGO, F.I.C., F.C.S., Barrister-at-law; and WILLIAM C. JAGO. London: Simpkin, Marshall, Hamilton, Kent, and Co., Limited. 1911. Pp. 908. Price 21*s.* net.

IT is difficult to find any topic of importance connected with bread which has been left out of consideration in this volume. The work is thorough from beginning to end, and no one writes with greater experience of the subject than the senior author. He wrote a work in 1886 which was responsible for much progress in bread-making; he reminded the practical baker of the scientific processes connected with the stages in his art, and exhorted him to apply scientific considerations to the making of bread, which after all is not a simple process. Rule of thumb often spelt failure, the application of scientific principles discovered to what failure was due, and nowadays the baker has no excuse left for a spoiled loaf. The importance of all this was steadily realised, education

in the matter of bread-making became a real thing, and the baker, if for only business reasons, had to adopt a system which he knew secured him a constant and standard product.

In 1895 Mr. Jago took considerable pains to bring his work up to a level consistent with the rapid advances which had been made in the science and art of bread-making. In his work published that year he entered fully into the part which chemistry and biology played in the conversion of flour into bread, while he carefully explained the dietetic significance of the various constituents of flour. His familiarity with the engineering side of bread-making was also obvious from the excellent monographs on the mechanics of the bakery. The book has now grown into a bulky volume, and in the preparation of the present work he has had the advantage of his son's assistance, Mr. William C. Jago, who has given considerable attention to the practical application of chemical methods in the mill and the factory, and who further has studied the applications of modern biology and bacteriology. The progressive baker will be grateful for the care which father and son have taken to keep their account of the subject in close touch with modern developments; but technology apart, there are many chapters which are of general interest. We may mention, for example, those in which the authors views are given on the bleaching of flour, flour and bread improvers, nutritive value and digestibility of bread, and standard bread, all of which form instructive reading in dietetics.

LIBRARY TABLE.

Die Neuralgien der Täglichen Praxis. By Dr. O. SCHELLONG, Königsberg, Prussia. Berlin: Julius Springer. 1911. Pp. 83. Price 1.80 marks.—The author describes in some detail the experiences of six years of general practice, so far as the varieties of neuralgia are concerned. Of some 2630 patients, no fewer than 458 suffered from neuralgia in one form or another. This seems an unusually high percentage, and if we are to judge from certain of the clinical histories furnished by the author the diagnosis of neuralgia may very well be questioned in some, especially since a fourth of his cases appear to have been among children. He subdivides his material into the different accepted groups of the disease, and supplies clinical instances of these different localisations. The longest chapter in the book is that on neuralgia of the brachial plexus, but there is no reference to cervical rib in this connexion. The paragraphs on treatment are for the most part taken up with the description of simple and palliative methods. The drug with which the author appears to have had the best results is quinine.

Psychiatrische Vorträge für Aerzte, Erzieher, und Eltern (Zweite Serie). By Prof. Dr. G. ANTON, Director of the Clinic for Nervous and Mental Disease in Halle. Berlin: S. Karger. 1911. Pp. 77. Price 2 marks.—This volume consists of five essays which may be supposed to be of interest for parents and teachers, as well as for physicians. They deal with subjects widely separated from one another, and the exigencies of his audiences (for the essays are reprinted from addresses read before societies) have compelled the author to deal with his material in a more or less popular way. The first essay is on the expression of the emotions in health and in disease; the second on epidemics of mental disturbance in past and present times; the third deals with the mental upbringing of children; the fourth is concerned with alcohol and its influence on offspring; and the fifth with the causation of epilepsy, and its operative treatment. The essays are readable and instructive, but somewhat slight, and not a little debateable matter is incorporated. Dr. Anton seems to have had unusually good results in his cases of chronic epilepsy which have been submitted to surgical interference. The second essay contains some curious but scarcely novel information on mediæval and modern epidemic hysteria, on lycanthropy and the were-wolf legends, on jumping mania, and kindred topics.

Five Months in a London Hospital. By KATHERINE ROBERTS. Letchworth: Garden City Press, Limited. 1911. Pp. 145. Price 2*s.* 6*d.* cloth, 1*s.* paper.—Written in diary form by a probationer nurse undergoing training in a maternity hospital, the author has daily set down her impressions of the strenuous work she had to carry out at the institution. She informs us that she has neither the strength nor time to describe in detail the work done by the probationer, as it required the combined energies of a hard-working and experienced charwoman, a housemaid, a "general," and a trained nurse to do it anything like justice. So hard was her work that her feet became swollen and blistered. "It seems to me," she remarks, "that what is badly wanted in London is a hospital where only ladies are admitted as nurses and sisters, where the charwoman's work is done by charwomen, the cooking and housemaid's work by cooks and housemaids, the nurses being only asked to do nursing, which in itself, if properly done, would fill up all their time." It is a pity that the name of the hospital referred to is not stated anywhere in the text; the writer evidently does not wish it to become known. Throughout the book there runs a vein of continual grumbling against the conditions under which the author had to work as a probationer midwife. The various difficulties are put forward in such a frank and open way that one is almost convinced that there is no exaggeration. The author, who is married and the mother of children, took up nursing because she liked it, and she is markedly sympathetic to her maternity patients, although she confesses in some of her anecdotes instances where her sympathy caused her to disregard the orders of the hospital and the medical staff. As the author shows a spirit of antagonism also to the nursing sisters under whom she had to serve it is impossible not to see that she is a biased witness. But parts of the book offer considerable food for thought, for they suggest what the internal economy of a hospital ought not to be; some passages are distinctly sensational, and if true require attention.

"*Medicus,*" *Guide Annuaire des Étudiants et des Praticiens (Médecine, Chirurgie, Odontologie, et Pharmacie).* Par A. ROUZAUD. Paris: 41, Rue des Écoles. 1911–12. Pp. 1696. Price 5 francs (4*s.* 2*d.*).—This useful book of reference is divided into six parts, in the first two of which are contained systematic information relative to the teaching of medicine, pharmacy, and dentistry in France, with lists of hospitals, asylums, scientific societies, students' societies, and the military, naval, and colonial services. There are also lists of the principal medical journals, both French and foreign, and of recent medical works issued by French publishers. The third part enumerates the principal foreign schools of medicine, with some historical account, a *précis* of their curricula, and the names of the faculties. The fourth part consists of a dictionary of the law as it affects medical men in France and of medical jurisprudence, arranged by M. Marcel Petit, advocate of the Paris Court of Appeal. The fifth part consists of a summary of the laws, decrees, and ordinances affecting the practice of medicine, pharmacy, and dentistry in France and her colonies, public health, hygiene, the sanitary police, the Public Assistance, and such like. The principal mineral watering-places, both French and foreign, are given and briefly described. Part 6 contains a directory, both alphabetical and local, of the medical men, dentists, pharmacists of France, as well of the civil and military medical men of the French colonies.

The Kala-azar Bulletin.—Owing to the great advances which have recently taken place in our knowledge of the various forms of leishmaniosis it was decided to issue, by arrangement with the honorary managing committee of the Sleeping Sickness Bureau, a publication on the lines of the *Sleeping Sickness Bureau Bulletin*, which has proved so successful and which has been found so helpful by all who have concern with trypanosomiasis of any kind. The first, or introductory, number of the new *Bulletin* has now been issued; it consists entirely of a "List of References" of the titles of some 900 publications relating to the affections known to be caused by leishmania, including kala-azar, as met with in India; infantile kala-azar or ponos, sometimes called infantile splenic anæmia, which is found on the shores of the Mediterranean or elsewhere; and Oriental sore, which is common in some parts of the East. This list has been carefully compiled by Mr. R. L. Sheppard, librarian to the Sleeping Sickness Bureau: it includes all the known works on this subject published up to the end of June, 1911. The future numbers of the *Bulletin* will be issued quarterly and will be under the editorship of Dr. C. M. Wenyon, protozoologist to the London School of Tropical Medicine. The *Kala-azar Bulletin* promises to fulfil a very useful purpose and will be welcomed by all who are interested in leishmaniosis.

New Year's Diaries and Visiting Lists.—To the medical man, as to other men, the Diary is practically indispensable, while the Visiting List has been devised especially for his convenience. From Messrs. Cassell and Co. we have received specimen copies of several of the well-known original Letts's Diaries for 1912. Those more especially suited to the needs of the medical man are the *Rough Diaries*, of which No. 31 contains a week on each opening of its foolscap pages (price 1*s.* 6*d.*, or interleaved blotting, 2*s.* 6*d.*); No. 32, of like size, which contains a week on each page and is interleaved blotting, for 1*s.* 6*d.*; and Letts's *Office Diary and Almanack*, No. 10, price 4*s.* 6*d.*, which contains six days on an opening. The foregoing diaries contain in the preface much useful reference information. The *Pocket Diary*, No. 111, is sold in three bindings, from 2*s.* to 3*s.* net. Letts's *Nurses' Report Book and Diary*, in red leather, price 2*s.* net, contains tabulated pages for case records and a week-to-the-opening diary, with cash account and memorandum pages. Finally, Letts's *Medical Diary* is a combined Diary and Visiting List, giving a week to an opening. The price varies according to binding, from 2*s.* 6*d.* to 4*s.* ruled for 54 patients, and from 4*s.* to 5*s.* 6*d.* ruled for 108 patients. The preface contains medical reference data and general information of special service to the medical practitioner. Letts's publications contain as usual an accident insurance coupon, and we are informed that claims amounting to £3500 have been paid to holders of these coupons. Another well-known publication is Smith's *Physicians' and Surgeons' Visiting List, Diary, Almanack, and Book of Engagements*, which has served the needs of the medical profession for 66 consecutive years. It can be obtained from the publishers, Messrs. Hazell, Watson, and Viney, 52, Long-acre, London, W.C., at prices according to binding from 2*s.* 6*d.* to 6*s.* 6*d.* The *Professional Pocket-book, Daily and Hourly Engagement Diary* (Rudall, Carte, and Co., 23, Berners-street, London, W.) is intended for musicians rather than for medical men, though it might conceivably be made use of by the latter as an engagement book. The open page contains a week in parallel columns of days, the hours being arranged down the left. The engagement pages are in three separate parts of four months each, enclosed in a leather case. From John Walker and Co. also we have received representative samples of their diaries. Walker's *Society Diary*, No. 48, is a handy book, in red cloth, giving a day to a page of excellent paper, and containing an engagement calendar, price 2*s.* 6*d.* Walker's *Loose Leaf Diaries*, especially the medical *Loose Leaf Pocket Book*, containing visiting list, cash accounts, treatment sheets, case sheets, temperature charts, and other useful pages, will commend themselves from the fact that their bulk can be reduced at pleasure by inserting only a few sheets and replacing them as necessary; moreover, the beginning of the following year can thus be carried simultaneously with the close of the current year. They are fitted with a simple device for opening the rings, and contain stamp, card, and other pockets. Messrs. Walker also send several other forms of diary of various sizes and styles, at prices from 1*s.* up, as well as the *Imperial* and the *Graphic Daily Wall Calendars*, in which the figures are boldly printed in colours. We have also received from Messrs. Borroughs and Wellcome a copy of the well-known *Wellcome Photographic Exposure Record and Diary* for 1912, which contains information of all kinds and in the fullest quantity relative to factorial and time development, machine, tank, or stand development, the oil pigment process, contact printing by artificial light, colour photography, the actinic values of lights, light tables, and the Wellcome exposure calculator, whereby it is possible to ascertain the correct exposure under any combination of conditions. Separate editions are published for the Northern Hemisphere and Tropics, the Southern Hemisphere and Tropics, and the United States, and intending purchasers should state which is desired. It can be had from all photographic dealers, price (in the British Isles) 1*s.*

JOURNALS AND MAGAZINES.

Annals of Tropical Medicine and Parasitology. Vol. V., No. 1. Liverpool: University Press. Pp. 131. Price 7*s.* 6*d.* net.—This number of the *Annals of Tropical Medicine and Parasitology* contains the following contributions: (1) Further Experimental Researches on the Etiology of Endemic Goitre, by Dr. Robert McCarrison; (2) Non-ulcerating Oriental Sore, with a New Similar Parasite in *Erthesina fullo* (Thumb), a Pentatomid Bug, by Captain R. Markham Carter, I.M.S.; (3) Infantile Leishmaniasis (Marda tal Biccia) in Malta, by Dr. A. Critien; (4) A Research into the Production, Life, and Death of Crescents in Malignant Tertian Malaria, in Treated and Untreated Cases, by an Enumerative Method, and (5) the Leucocytes in Malarial Fever, a Method of Diagnosing Malaria Long After it is Apparently Cured, by Dr. David Thomson; (6) Note upon Yellow Fever in the Black Race and its Bearing upon the Question of the Endemicity of Yellow Fever in West Africa, by the late Sir Rubert Boyce; (7) On the Amœbæ Parasitic in the Human Intestine, with Remarks on the Life-cycle of Entamœba Coli in Cultures, by Dr. H. B. Fantham. (8) Some Further Observations on the Tsetse-fly, described in these Annals as Glossina grossa, by Professor Robert Newstead; (9) On the Correlation between Trypanosomes, Leucocytes, Coagulation-time, Hæmoglobin and Specific Gravity of Blood, by Mr. Vishnu T. Korke. 1. Dr. McCarrison gives an account of some experiments which confirm and extend observations communicated by him to the Royal Society in November, 1908. His paper has already been referred to in THE LANCET. His experiments are very comprehensive, and his conclusions are cautious and just. Indeed, he might well have claimed that he has shown that it is practically certain that endemic goitre, at least in the district in which the experiments were carried out, is due to a living organism, whereas he only claims that this is probable. 2. Captain Carter contributes a paper which is suggestive and contains descriptions of two very interesting series of experiments. He shows the existence of many similar points in

the cultural characteristics of the parasite causing the non-ulcerating oriental sore and those of another parasite which he discovered in an insect commonly found throughout India and eastwards as far as Japan. His methods are ingenious, and though he does not demonstrate that the new parasite in the insect dealt with has anything to do with oriental sore, his experiments suggest that man may probably be another host. Considering the second part of the paper as independent of the first, as in most respects it actually is, an inversion of the usual method of attacking parasitic diseases is suggested—finding the parasite first and the disease afterwards. A most original point about the paper is the way in which Captain Carter shows that this protozoon, demonstrably parasitic in a particular insect, is possibly, or even probably, parasitic in man, though not in rats and some other mammals. 3. Dr. Critien's paper on Infantile Leishmaniasis (Marda tal Biccia) in Malta, contains a number of careful observations upon this disease. His facts as to distribution and some other points, however, though numerous, are not sufficient to permit definite conclusions, and he claims no more for them than that they are suggestions as to the lines upon which further investigations are most likely to be profitable. He "puts on record" that marda tal biccia and infantile kala-azar are one and the same disease. 4 and 5. The two papers on malaria by Dr. David Thomson give in detail a large number of most laborious observations. Some of them are of undoubted value. Perhaps the most interesting is the fluctuations in the percentage of leucocytes which persist in the patient, notwithstanding ample treatment with quinine, for a considerable time, sometimes for several months, after apparent cure. The nature of this fluctuation depends upon the nature of the fever from which the patient has suffered. 6. The note upon the relative immunity of strange and native races to yellow fever in countries where the disease is indigenous, by the late Sir Rubert Boyce, is of considerable interest, particularly to students of heredity Though many may not agree with the author as to the nature of the immunity enjoyed by the native races, they will certainly welcome the facts collected and thus placed at their disposal. 7. The bulk of Dr. Fantham's paper is occupied by a useful sketch of the known parasitic amœbæ of the intestine of man and a brief but good critical review of the previous observations upon them.

New Inventions.

IMPROVED MEANS OF DILATING CERTAIN PASSAGES.

FIGS 1 and 2 are instruments which, I submit, possess many advantages. Fig. 1 is a uterine and Fig. 2 is a male urethral dilator. Hitherto the great defect in expanding dilators was that we had no means of gauging force. Hence dilatation to desired degrees was at the expense of splitting—a heavy penalty. We cannot judge force by screws, nor is hand pressure so good as untiring gentle elastic pressure. Fig. 1 dilates the cervical canal by means of the elastic expansion of its long arms A, thus antagonising tonic resistance by tonic pressure. There is a scale not shown. The instrument is put into action after introduction by pressing the handles together to the extent desired and fixing them at that by the fly nut. B lies against the external os and affords the *point d'appui* for gauze packing to keep the instrument *in situ*, the handles being supported on a pillow. Thus tents, always a nuisance and sometimes septic, may be dispensed with. Rapid dilatation may, of course, be used. Fig. 2 is a substitute for Kollmann's dilator. The posterior half of the anterior urethra is a funnel, widest at the bulb. No instrument ever used is capable of distending this widest part to the full extent without splitting the narrow part of the funnel. No instrument satisfactorily dilates the bulb, the chief site of infiltration, worst beginning strictures, and gleet. Nor do instruments passed beyond this site distend it owing to the smallness of bulbo-membranous junction. The arm E is long, hence it extends to the extreme end of the spongy urethra. Moreover, the arrangements of the semi-bulbs of the instrument permit them to pass through a narrow meatus, thus constituting a

FIG. 1.

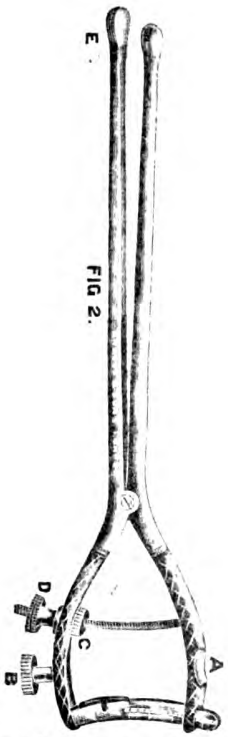

FIG. 2.

large distending body behind it, and a urethrometer if desired. This dilator, like the uterine, can be actuated by finger-pressure on A and B, or by screw through D; there is a millimetre scale. The character of the arms is such that while the whole anterior urethra is uniformly dilated there is no splitting. The desired expansion is fixed beforehand by the nut C, and expansion is taken to this extent or not according to the resistance conveyed to the fingers or according to the patient's sensations.

The instruments were made originally by myself, but are now made in a more perfect way by Messrs. Arnold and Sons.

Finsbury-pavement, E.C. JAMES MACMUNN.

WEST END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM, PARALYSIS, AND EPILEPSY.—On Dec. 1st a number of ladies met at 5, Bryanston-square, on the invitation of Mrs. Ian Malcolm, to take steps for the formation of a ladies' guild. The chair was taken by Colonel the Hon. Charles S. H. D. Willoughby, treasurer of the hospital; the secretary, Mr. D. D. Kirkaldy, and the matron, Miss Catharine E. A. Thorpe, were also present, and a number of influential ladies. The chairman opened proceedings by giving a sketch of the hospital's work and by showing the service a ladies' guild would be to the hospital. The matron then entered into further details regarding the advantages of such a guild, whose subdivisions might help the hospital in obtaining gifts of vegetables, flowers, poultry, and clothing. A resolution that a ladies' guild be formed was then carried unanimously and the following officers were elected:—President, Lady Violet Brassey; honorary treasurer, Colonel Willoughby; honorary secretary, Miss Broadhurst; honorary secretary of Vegetable League, Lady Guernsey; honorary secretary of Clothing and Linen League, Miss Easton. A committee was formed consisting of Mrs. Ian Malcolm, Mrs. Ferdinand Huth, Mrs. C. A. Ballance, Mrs. Harry Graham, and the honorary secretaries.

THE LANCET.

LONDON: SATURDAY, DECEMBER 16, 1911.

The National Insurance Bill.

THE National Insurance Bill, receiving probably no modification at the hands of the House of Lords, will become law within the next few days, and the medical profession has to resolve what course should be pursued. We must recollect that no one course can be equally acceptable to all the members of a highly organised calling. In this elaborate and far-reaching measure the interests of some practitioners are affected in one manner and the interests of other practitioners are affected in a totally different manner by the same section or sub-section of the measure. The Bill is quite clear with regard to the benefits that are to be received by the insured from the medical profession, quite clear that in return for definite contributions free medical service is to be supplied, but quite vague as to the payment of those who are to supply it. For these reasons, as well as because of a too general committal of the profession to an extension of the contract system, we have always considered that the medical profession should have pointed out from the very beginning that it would be impossible to arrange a satisfactory scheme of either distribution of medical benefits or payment of medical men unless adequate time were afforded for the taking of medical opinion; especially was a proper investigation necessary of the conditions under which much medical practice was performed in this country. Such an investigation would have taken note of the capital sunk in the purchase of practices and of the income derivable in certain proportion from contract practice and in certain proportion from private patients; it would have estimated the amount of ground that a practitioner could cover in fairness to himself and in relation to his income; it would have ascertained the proper proportional number of the profession to the general population; it would have sifted the statements of those who proposed to adopt a measure for the English, Scottish, and Irish because it did (or did not) suit Germany. Such an investigation as this, made by people on whom the medical profession could rely, was wanted; for it was a revolution in medical practice and not an adjustment of our earning arrangements that was contemplated under the Bill.

But no. No stand was made by the medical profession for the necessary time in which to consider the Bill, although from the first it was clear that unless proper time was given the situation in which now we are placed would probably occur. Those in actual practice of the sort that must be affected were as little consulted as those having charge of the medical education of the country, or representing great medical corporations or great university faculties. A majority of medical men was found to believe that there was no peril in accepting the Bill in detail as well as in principle, if certain modifications were introduced. Of course, every man in this majority of medical men who demanded the recognition of what are called the six cardinal points was not solidly in favour of demanding all six points for the same reasons or with the same fervour—a weakness which could hardly fail to escape the eye of those responsible in Parliament for the passage of the Bill. The opposition to details was itself detailed. Similarly it was clear to all with experience of affairs that at least one of these six cardinal points would not be granted as such, or, at any rate, would not be incorporated in the Bill as such. But the prepossession in favour of the Bill, due to the excellent principles underlying it, no less than the excellent things in it, obscured many eyes. As the circular of the British Medical Association dated Dec. 11th, and published on p. 1726 of this issue of THE LANCET, shows, the Association decided on June 1st to adopt the policy expressed in the six cardinal points which have so often been set out. Given these points the Association decided to help in the working of the Bill, a policy which it is claimed is absolutely unchanged. Moreover, it is stated by the chairman of Representative meetings and the chairman of the Council of the Association to have been successful, in that by the efforts of the Association the Bill has now been so amended that there is no legal barrier against the profession securing the fulfilment of its entire policy as indicated by the six cardinal points. That may be so, but it would certainly require a lawyer to make this statement absolute; and we fear that any of our readers, desiring in a dispute to obtain the rights which he might thus believe to be reserved for him, would have considerable difficulty.

The position then is that a Bill, which no medical man should have wanted until it had been entirely adjusted upon professional lines and with due regard to existing conditions, will become law in a few days; that instead of such wholesale adjustment a policy of detailed amendments has been adopted by a majority of the medical profession; but that the measure is passing into law without there being any certainty that the very points are included concerning which the majority of the medical profession are, or rather are supposed to be, solidly positive. We can hardly wonder that the apprehensions of the profession are finding vent in such important meetings as that which is being held in Manchester as we go to press, and that which is announced to be held in London on Tuesday next under the chairmanship of Sir W. WATSON CHEYNE. We hope that the collective force and wisdom of these meetings—and there will be many like them—will not be dissipated in mere bewailing of the present conditions, or in resentment at any particular persons or institutions. The energies of those who promote them and those who are present at them can well be turned to action, either by the strengthening of such organisation as we have, or by the formation of some representative, if temporary, authority, which, by taking a line of independent criticism, may

reinforce medical men in all just demands, and perhaps avert some of the evils of impending agitation. A voice that can clearly have nothing to gain by pleasing any party in the Government or any section in the profession, and that cannot be accused of serving private interests, may bring confidence to many, may reconcile some of the conflicting views, and may supply that leadership which Sir ALFRED PEARCE GOULD asks for in his weighty letter in this issue of THE LANCET.

The Propagation of Plague without the Aid of Infected Rats.

"No rats, no plague," has been for some years the confident assertion of well-known experts at home and abroad. It was as far back as 1899 that Dr. P. L. SIMOND, who had been studying plague in India, laid before the Academy of Medicine at Paris his ingenious explanation of the mode in which plague was transmitted from the infected rat to man through the agency of the flea. Though at first this opinion met with some adverse criticism it has stood the test of time, and the theory he propounded in 1899 has now found general acceptance, having meanwhile been confirmed by laboratory researches, particularly those of the Advisory Committee for the Investigation of Plague in India. According to Dr. SIMOND, plague could not become epidemic in a locality until the rats had become infected. In India and elsewhere the prevailing type of the disease has hitherto been the bubonic, and although occasionally a proportion of pneumonic cases have been observed in which infection seemed to be conveyed by personal contact, they were not regarded as likely to give rise to any considerable spread of the disease. In the light of some recent events, however, it seems likely that we shall have to modify these views. In the virulent plague epidemic which devastated Manchuria in the winter of 1910–11, and which carried off more than 45,000 victims in a few months,[1] it is reported on the highest authority that during the whole course of the epidemic not a single plague-infected rat was discovered, though careful and prolonged search was made, and many thousands of these animals were examined in the affected localities by competent observers, including Chinese, Russians, and Japanese.

Recently two experts have discussed this epidemic, and each has put forward a different explanation of its rapid diffusion, notwithstanding the absence of infected rats. Dr. SIMOND, to whom we have already alluded, published an article in the July number of the *Revue d'Hygiène* entitled "L'Épidémie de Manchourie en 1910–11, et l'État de nos Connaissances touchant la Transmission de la Peste Pneumonique"; and at the October meeting of the Epidemiological Section of the Royal Society of Medicine in London a paper on Plague in Manchuria was read by Dr. REGINALD FARRAR, who was one of the British delegates at the International Plague Conference held at Mukden last April. Both of these experts are in entire agreement as to the main facts connected with the outbreak. It began in October, on the borders of Eastern Mongolia, among coolies employed in trapping the tarabagan, a species of marmot the fur of which is now in great request to imitate sable. For many years an epizootic has from time to time occurred among these animals, and lately this disease has been found to be plague. The tarabagan in past years has been hunted by the native Mongols and Buriats, but owing to the increased demand for the skins some thousands of Chinese coolies had been brought for this purpose from North China. These men were returning eastwards to their homes at the end of October last year, and some of them were attacked by plague of the pneumonic type. Crowded close together in railway carriages they travelled along the Eastern Chinese line, and as they passed through Manchuria they were joined by an immense number (not far short of 90,000) of Chinese coolies who had been employed on the Manchurian farms in the harvest of the soya bean and other crops. The Southern Manchurian Railway passes through a number of towns in the Liao-tung peninsula to Dalny (or Dairen), where the bulk of the coolies cross the Gulf of Pechili in junks or steamers to Chefoo and other ports in the province of Shantung, where plague outbreaks also occurred on arrival of the coolies. The railway carriages were crowded day after day with these men, and many of them slept at night in wayside inns where it was impossible to provide them with adequate accommodation. These coolies do not wash themselves when winter sets in, and they work and sleep in the same clothes, which soon become coated thickly with dirt. They had to sleep in the inns, packed in rows side by side, as Dr. FARRAR says, "like herrings in a barrel," in a confined and artificially warmed space, all fresh air being carefully excluded on account of the keenness of the cold. The majority of those attacked by plague in Manchuria were of this coolie class, and the epidemic area was almost entirely confined to the towns in or near the railway zone. Dr. SIMOND attributes the rapid spread of this virulent plague to the agency of human fleas. He points out that plague contracted from the tarabagan is almost always of the pneumonic form, and that plague bacilli in such cases are very soon to be found in the blood where the human flea can obtain a supply wherewith to infect other persons whom they may bite. The condition of the coolies' persons and clothing would be favourable to the flea, and the warmth of the man's dirty body would counteract the benumbing effects of the intense cold upon the insect. It is fair to Dr. SIMOND to point out that in his original communication to the Academy of Medicine in 1899 he spoke of the human flea being capable of conveying plague infection from man to man. Dr. FARRAR takes a different view, and accounts for the rapid spread of this disastrous outbreak by personal infection, the plague bacilli being sprayed into the air around the patient by the act of coughing. In view of the overcrowding of railway carriages and wayside inns during the return journey of the thousands of coolies, and considering the coldness of the weather and the exclusion of fresh air from the carriages and sleeping apartments, the conditions were altogether favourable for the conveyance of infection from a single patient to many other persons. Some of the experts among the international delegates at Mukden exposed plates in the vicinity of plague patients and succeeded in obtaining cultures of plague bacilli from the droplets coughed into the air by the sick men.

[1] THE LANCET, April 29th, 1911, p. 1152.

We do not deny the possibility of the truth of Dr. SIMOND'S contention, though he himself admits that there has been no evidence collected showing that fleas were present at all, or that they were present in any great numbers on the bodies of the plague patients or the coolie travellers. It appears to us that on the whole Dr. FARRAR'S view is the more probable one. The epidemic is admitted to have been of exceptional virulence, killing practically all who were attacked. The exaltation of the virulence of the infection may have been due, as suggested, to its being derived from the tarabagan, but it is possible the largeness of the dose of infection received by the victims may have had a share. When a patient with pneumonic plague coughs a spray of bacilli is shot into the air around him. A healthy person in the vicinity would inhale these microbes in greater number probably than they could be injected into his blood by fleas. The site also of the inoculation of the virus is important. When the infection is received direct into the respiratory tract it is likely to prove far more serious than if it had been inoculated through the skin. When the epidemic developed no provision had been made for treating or isolating the sick, and there was no sanitary administration to prevent the extension of the outbreak. It is hardly necessary to refer to the ghastly horrors that supervened, when whole households died, or if any survived they fled from their homes in panic, many of them to die on the road. The sick were left to perish untended, or were thrust out by their terrified relatives to die in the streets, where their bodies were devoured by dogs or birds of prey. All trade and commerce came to a standstill. There was no one to bury the dead; the ground being deeply frozen made this, indeed, an impossible task; the corpses accumulated in the towns till they were piled up in heaps and had ultimately to be burnt. At the end of March the outbreak ceased almost suddenly. This, Dr. SIMOND says, was due to the diminution in the number of fleas, but Dr. FARRAR attributes it to the enforcement of appropriate preventive measures. Dr. SIMOND, however, points out that these measures were unequally enforced, and that plague ceased just the same in localities where nothing had been done as in those where the authorities had acted with energy. The dispersion of the coolies no doubt reduced the amount of susceptible material; it is possible that the end of the wintry weather and the consequent elevation of the temperature led the people to admit sunshine and fresh air into their formerly ill-ventilated houses. It is, we think, very probable that overcrowding, uncleanliness, and want of proper ventilation played a part in favouring the spread of the epidemic. The serious character of the outbreak was aggravated by a combination of circumstances, among which lack of hospital accommodation, and want of sanitary and medical administration, played a part. This plague epidemic in Manchuria seems to show that plague can in certain circumstances become epidemic without the agency of infected rats. There is also the suggestion that possibly a secondary pneumonia occurring in a bubonic plague case might infect others, and that the infection "breeding true" might spread rapidly as pneumonic plague without any assistance from infected rat-fleas.

The Racial Importance of Venereal Diseases.

THE public even yet do not recognise to the full the vast importance to the community of the prevention of venereal disease. There can be little doubt that tuberculosis does not cause more than a small proportion of the pain and misery which result from venereal disease. While the members of the medical profession are well acquainted with the importance of these diseases, the general public know little or nothing of their wide prevalence or of the severity of the results which are produced. We publish on p. 1692 the concluding section of a valuable presentation of the position given in a paper by Dr. DOUGLAS WHITE and Lieutenant-Colonel C. H. MELVILLE, R.A.M.C., at the Annual Congress of the Royal Institute of Public Health held in Dublin in August last. In this paper are set forth clearly the disastrous prevalence of these diseases, not only in the army and navy of all countries, as testified by statistics, but amongst the civil population, though here the exact amount of mischief must be more doubtful. However, according to the authors and by a moderate estimate, there are in this country probably more than half a million fresh cases of venereal disease annually. This is an appalling number, especially when the consequences of syphilis and gonorrhœa are considered. The effect of gonorrhœa in causing sterility and chronic invalidism in women is only now beginning to be fully recognised, while we are ever finding more and wider extensions of the activity of the syphilitic poison. The danger is one that must be faced, and not put aside or hidden as unfit for discussion, as is the usual method in this country.

Fortunately, there is evidence of a decided diminution in the extent of these diseases amongst both the military and the civil population, and this is attributed by Dr. WHITE and Lieutenant-Colonel MELVILLE to the general improvement of moral tone and increase of sobriety, for there can be little doubt that a great amount of venereal disease is contracted during drunkenness. The question of the value of various methods for the regulation of prostitution is considered in the paper, and we are bound to agree with the authors that even in those countries where regulation has been most complete the results have been unsatisfactory. At the Brussels conferences of 1899 and 1902 the majority of the speakers were in agreement with the view that regulation had failed, for it does not succeed in preventing clandestine prostitution, by which much of the venereal disease is spread. Several continental countries have given up the attempt to regulate prostitution, and there can be little doubt that as a whole the system has failed not only to eradicate but to prevent the evils it was designed to cope with, although in certain and particular circumstances it proves efficacious. Alluding to the question of compulsory notification, the authors suggest that venereal diseases should be notified in the same manner as the other infections which are notifiable, but the objection to this idea is obvious. Notification would be followed by communication of the name and address to the authorities, and this would certainly lead to concealment by

the patient of his or her condition, and thus would be defeated the very object for which notification had been established. Yet a modified system of notification may be applicable, no names being given; by these means we should be in a position to form a clear idea of the real number of cases, and we should be able to form an estimate of our progress. This anonymous form of notification is not new, for it is already in use in Denmark, Norway, and elsewhere.

In every hospital there should be accommodation for the treatment of venereal cases, both as in-patients and as out-patients. If these means were adopted there would at first appear to be an increase in the number of cases, but before long this would be changed to a decrease. Further, the recent advances in the treatment of gonorrhœa, and even more of syphilis, can give results not hitherto attainable. The gain to the community by the diminution of these diseases would more than repay the cost to the State. Some useful suggestions for the diminution of syphilis were given in the second of the lectures by Major H. C. FRENCH, R.A.M.C., at the Royal College of Surgeons of England in November last.[1] He is in favour of confidential notification applied to both sexes; the segregation of diseased persons in hospital for a few weeks during the early contagious period of the disease; and lastly, efficient in-patient and out-patient treatment. By these means syphilis has been almost stamped out at Malta during this year. In 1909 there were 87 freshly contracted cases amongst the troops there; in 1910 there were 35; and in 1911 only three or four cases have occurred. The matter is of the first moment, yet it is unaccountably neglected by our legislators. Much may be done in several ways, but it is probable that some form of notification would be of very definite assistance. Even though it be not possible to eradicate venereal diseases, their extent can certainly be diminished, the evil, suffering, and death due to them can be reduced, and the race thus materially benefited.

Annotations.

"Ne quid nimis."

THE HEALTH OF TELEPHONE OPERATORS.

ENTIRELY apart from its humanitarian aspect, the efficiency of the worker is always a matter of the first importance to the employer. It is the part of the worker to bring to his task a bodily capacity adequate to the work to be performed, and so to direct his life that it shall not become impaired by any fault of his. On the employer it is incumbent, in the first place, not to accept candidates who can be recognised as being below the standard of capacity, and, next, to arrange the conditions of work, with a view to lessening the tax on the worker's vitality. In the case of public services of the character of the telephone service, the personal relations between the individual members of the public and the employees constitute a third important factor in the efficiency of the worker. It is satisfactory to note that, in accordance with the report of the committee of medical men appointed to inquire into the working conditions of the Post Office telephone employees, all these factors have received careful attention. The report, which was issued as a White Paper on Dec. 5th, was accompanied by a circular from the secretary of the Post Office summarising the recommendations of the committee and, for the most part, laying down the necessary steps to be taken in the proper quarters to give them effect. In the selection of candidates great care is urged to exclude such as are unfitted by markedly anæmic conditions and those of unstable nervous equilibrium. A moderate and ordinary form of anæmia, however, need not necessarily exclude, for the first of the two probationary years will suffice to enable the morbid condition to be cured if easily curable, or to establish its depreciating effect before a permanent engagement is entered on. But a sound nervous system is essential, because the telephonist is constantly using three special senses—namely, speech, hearing, and sight. This, although no injury to the senses themselves was noted, must be very wearing because of the strain on attention inherent in the work; and because the telephonist, instead of dealing, as the telegraphist does, directly with another skilled operator, deals directly with the public, "whose knowledge of the method of working," says the report, "is limited and whose methods, manner, and temper are always diverse and sometimes unpleasant. She is constantly smoothing out difficulties, and is often the subject of abuse or reproach, whilst it is necessary for her to be businesslike, tactful, and courteous under all conditions." Another strain upon her physical powers is the constant jumping up and down and reaching out entailed by her work. Of the employer is demanded consideration for the periods of work and the suitability of the head gear and breast gear. Of the three methods of allotting tours of duty at present in use the proposal to reduce the working day of continuous service from eight or eight and a half to seven and a half hours is postponed. Alternate days of long and short duties are to be abolished, and as regards "split duties," the intervals between a split attendance are to be made either as short or as long as possible. The committee's recommendation that the annual leave should be extended to 21 days is postponed. As to the gear, the committee have wisely suggested that it should always be personal to the girl herself, and that she should be permitted to wear it in any convenient fashion consistent with working efficiency. Steps, moreover, are to be taken to reduce the weight of the receiver and transmitter and to improve the accommodation provided for operators, while the suggested adoption of a rotation in the three main duties—subscribers' boards, junction boards, and trunk lines—is met by the secretary with what appear to be very weighty objections, of which not the least is the usefulness of the knowledge acquired by the operator as to the needs and peculiarities of individual subscribers. The report cannot, of course, deal effectively with the third factor in the induction of ill-health in the telephone operator, especially nerve-strain—namely, the behaviour of the public. It is to be hoped, however, that the widest publicity will be given to this point, in order that it may be instilled into the public mind that forbearance, lack of irritability at slight mistakes, and courtesy may do much to mitigate the rigours of a very trying service which in these days we could hardly get along without.

COLD BATHS IN DISEASES OF CHILDREN.

IN the *Canadian Practitioner* for November Dr. James Newell has published a paper, read at the last meeting of the Ontario Medical Association, on the value of the cold bath in the treatment of diseases of children. We noticed last year a paper by a South African practitioner, Mr. M. G. Pearson, advocating in infantile convulsions, instead of the usual warm bath, a cold bath, on the ground that convulsions are due in all cases to pyrexia.[1]

[1] THE LANCET, Nov. 18th, 1911, p. 1389.

[1] THE LANCET, July 16th, 1910, p. 180.

He reported several cases in which this treatment proved most successful. He has found the treatment equally successful in prevention. He is in the habit of telling the parents of acutely ill children that there is no fear of convulsions as long as the temperature is under 102° F.; that above 103°, no matter what the illness, there is extreme danger of convulsions; and that the temperature should be watched and, if necessary, reduced by bathing. He compares convulsions to the boiling over of a kettle, which is preventable by similar means. In a correspondence which followed[2] the value of this method was confirmed. For over 30 years Dr. Newell has employed the cold bath as a favourite treatment in children's diseases attended by a high temperature and irritability of the nervous system. When a child is in convulsions, rigid, and stertorous, with a temperature of 104° or 105° F., he finds that the happiest results are obtained from a cold bath of 75° or 80°, followed by affusion of cold water to the head, and supplemented by friction of the limbs and body, till the rectal temperature drops to 100°, when the child is removed from the bath and wrapped up, with hot-water bottles applied to the extremities if they have become blue and cold. The treatment is similarly useful in the acute febrile attacks of children with rapid rise of temperature and nervous twitchings, of which the cause may be unknown. Dr. Newell recommends this treatment as preferable to administering the coal-tar antipyretics, which are apt to be followed by cardiac and nervous depression as well as by destruction of hæmoglobin. The cold bath, on the contrary, has a stimulating action on the heart and respiration, producing an increase of blood pressure and deeper respirations. Oxidation processes, diuresis, and other metabolic changes are increased and the number of red blood corpuscles rises.

"THE EXTERNAL MALLEOLAR SIGN."

IN the *Interstate Medical Journal* for July and October Professor C. G. Chaddock, of St. Louis, has described a new sign of organic disease of the spino-cortical reflex paths, which he terms "the external malleolar sign." It somewhat resembles Babinski's sign, but seems to have certain advantages of its own. It consists in extension of one or more or all of the toes, with or without "fanning," when the skin below the external malleolus is irritated. It can almost always be obtained when Babinski's sign is present, and, on the other hand, it occurs when Babinski's sign is absent, and then it is a reliable sign of organic disease of the central nervous system. Professor Chaddock has found it present without Babinski's sign in fracture of the skull, transitory unilateral cerebral lesions, old hemiplegia, general paralysis, and lesions of the cord. He never found it in peripheral lesions or in pure tabes. He has seen it develop alone to be joined by Babinski's sign and persist after Babinski's sign has passed away. The external malleolar sign is obtained as follows. The patient lies in bed on the back, with the lower limbs relaxed and extended. If possible, especially in doubtful cases, the limb to be tested should not be compressed or touched in any way except at the point of application of the stimulus. The sign may also be tested with the patient sitting in a chair and the limb resting on the knee of the examiner, who sits at a convenient distance. Irritation of the skin is best performed with a rather dull steel point. In the groove which outlines the external malleolus the point is drawn from behind forwards until the depression between the malleolus and cuboid is reached. This depression seems to be the most excitable point. The irritation should be varied from slight stroking to rather severe scratching with considerable pressure, but it is never necessary to abrade the skin or cause pain. Normally this stimulus causes no movement whatever of the toes, but it may cause reflex contraction of the muscles of the thigh like that produced normally when the sole of the foot is irritated. The abnormal reaction consists in extension or fanning of one or more or all the toes. In a few cases Professor Chaddock has observed a movement of flexion, and in these there was organic disease of the central nervous system. He therefore considers that flexion has the same pathological significance as extension. Care must be taken not to confound voluntary movements of the limb to escape the irritation with those excited reflexly. A striking peculiarity of the external malleolar sign is the fact that with a unilateral Babinski's sign it is the rule to find it on both sides. Often two toes—for example, the second and third—are extended together, the others remaining unmoved—a movement almost, if not quite, impossible voluntarily. Fanning of the small toes, without extension of the great toe, is likewise practically impossible voluntarily. So also is abduction of the little toe, the others remaining unmoved. Other peculiarities which mark the abnormal movements are the uniformity of the response with repeated application of the stimulus, their production from a definite skin area, most frequently from the depression mentioned, and an electric-shock-like quality. Movements of escape from unpleasant irritation occur indifferently from other areas. The following are some examples of the external malleolar sign. A youth, aged 20 years, fell from a wagon on the right side of his face on August 23rd, 1911. He was unconscious from the time of the fall until the morning of August 27th, when his pulse was 54 and his temperature normal, and he complained of severe unlocalised headache. Both eyes were black, the pupils were normal, and the deep reflexes were normal with a slight indication of ankle clonus. Babinski's sign was absent, but infra-malleolar irritation caused extension and fanning of all the toes on both sides. He became worse, and on August 30th the temperature was 101° F. Babinski's sign was present on the right side, and there was paresis of the left side of the face. Because of the presence of Babinski's sign on the right side, left subtemporal decompression was performed on the 31st, and scarcely any increase of tension was found. Right decompression was then immediately performed. Great pressure with subdural blood was found and drainage was established. The patient was immediately relieved, the pulse rose to 72, and Babinski's sign disappeared, but the right external malleolar sign persisted. A man, aged 38 years, with a history of syphilis, was mentally disturbed and suffered from severe headache. There were Argyll Robertson pupils, of which the left was the larger, double slight ankle-clonus, the external malleolar signs on both sides, and normal plantar flexion on irritation of the toes. He improved under mercury but remained demented, and died in a cerebral seizure. The necropsy showed softening of the left temporal lobe and of all the white substance of the right hemisphere.

SUBLUXATION OF THE PENIS.

TWO cases of this rare form of injury having come under his care within two months, Major N. R J. Rainier, I.M.S., has recorded them, with brief notes of five others alluded to in the literature, in the *Indian Medical Gazette* for November. His reason for doing so is that he considers the description of the injury found in text-books potentially misleading. His first case was that of a boy of 14 who had been gored in the perineum by a bullock. The scrotal raphé was lacerated and both testicles were prolapsed. These were cleansed and replaced, the wound was sutured, and 8 ounces of bloody urine were withdrawn by catheter. Three days later pain was experienced in passing urine,

and it was found that urine was issuing from the wound (which had broken down) as well as from the apparently normal penis. Closer examination showed that the "penis" consisted only of a sheath; the glans penis, which was lying above and behind the testes, was drawn down into this sheath, to which it was accurately stitched after removal of the foreskin. Four years later the cure proved anatomically and functionally satisfactory. A second case, occurring in a lad of 16, was also attributed to the onslaught of a bullock, but in this instance the very improbable story given was that the animal had gored him through the foreskin, the penis disappearing at once. In this case also the penile sheath was empty, the body being felt as a firm object at the scrotal junction. The displacement was reduced and the penis retained in position by strapping, a device which seems to have been successful. The point to which Major Rainier draws special attention is the condition of the empty sheath: he says that it feels like a thickened piece of small bowel. In all the cases cited by him the displacement of the body of the penis was apparently overlooked at the first examination. In recent cases the treatment is replacement with or without incision, while in cases of some standing a plastic operation may be necessary. Apparently the results are satisfactory as a rule.

"THE SURGEON'S LOG."

BOOKS of travel are many and of various excellence. At the one end of the scale come such works as "Eothen" and "The Monasteries of the Levant," to say nothing of Herodotus. At the other—but they are many, and it is kinder not to particularise. This book by Dr. J. Johnston Abraham is certainly one from the right end. Dr. Abraham not merely sees but observes. Having travelled as surgeon on a high-class tramp steamer to the Far East, to Singapore, Japan, Java, Celebes, and home again, he gives us in "The Surgeon's Log"[1] the results of his observations and impressions, written in easy, pleasant English, with an alert sense of humour, and the eye of an artist. Everyone who is blessed with any imagination feels the effect on the mind of the great spaces of the desert and the sea. "When we laughed we laughed softly, for the feeling of immensity was over us," says Dr. Abraham, in recounting his feelings at the sight of the desert from the Suez Canal, "and we could intuitively understand how, nurtured in such great vastnesses, the Semitic mind had risen above the futile polytheism of the Greeks, and evolved the grand conception of a vast, omnipotent, omniscient, and omnipresent God, with its necessary corollary, 'there is no God but God.'" And here is a picture of sunset in the Canal. "Slowly the Turneresque effect rose to a climax, until the sinking sun touched the rim of the horizon, sank rapidly, and disappeared; and then as if at the touch of a wand, the gold, the rose, the blue, the green, melted to all the shades of grey, a little breeze sprang up from nowhere, and the soft mantle of night swept in layer after layer across the sky." Dr. Abraham records but little of his medical experiences—very possibly there were none worthy of special mention; but his impressions of the places visited, of the scenery, the peoples, the trade, the political possibilities of the Dutch East Indies, the fishes, animals, birds, and flowers, are all set down in a simple and yet vivid manner. His comparison of Chinese honesty with Japanese subtlety—we mean in the commercial field—is judicially set forth. We do not know if it is still so to-day, but certainly a decade or two ago Chinese clerks were largely employed in the banks and counting-houses of commercial firms in Japan. Dr. Abraham's explanation thereof, together with his prophecy that in the future the one nation will become as honest as the other, is convincing. The author seems to have been most fortunate in his shipmates, who are all drawn with a loving hand, especially the chief engineer, a worthy peer of Kipling's MacPhee, while the captain must have been a delightful person and one, moreover, who knew a good dinner. Dr. Abraham's description of the Javanese "rijst-tavel" calls forth a sigh for the East, the deeper if one has been there already and "hears the East a-callin'" with its mysteriously seductive voice. "The Surgeon's Log" will doubtless prove enjoyable reading, more especially to those members of the medical profession who have made one or more voyages as ship's surgeon—a life that is not without its delights, particularly on the oriental and southern routes. Dr. Abraham talks of "one bell" as being sounded at 11.45 P.M. and 5 45 P.M. We thought that "bells" are sounded only at the hours and half-hours, not at the quarters, "eight bells" being at the hours of 12, 4, and 8.

PERFORATION IN INTESTINAL TUBERCULOSIS.

ALTHOUGH intestinal ulceration is a common complication of chronic pulmonary tuberculosis, perforation has seldom been observed. In the *American Journal of Medical Sciences* for November Dr. John M. Cruice has published an important paper on tuberculous perforation of the intestines, the result of a study at the Henry Phipps Institute. Of 475 necropsies on the subjects of pulmonary tuberculosis he found intestinal ulcers in 313 (65·9 per cent.). In 13 (2·7 per cent.) there was perforation. Of these, 10 were "complete" and 3 were "incomplete" perforations. This distinction was introduced by the late Dr. Samuel Fenwick, who defined the former as perforation directly into the peritoneal cavity causing either acute peritonitis or local abscess, and partial perforation as cases in which adhesions had formed with some coil of intestine before the ulcer had perforated. There is, therefore, no extravasation of fæcal matter and no acute general peritonitis. Sometimes ulceration takes place through the adherent coils of intestine, forming a fistula. Dr. Cruice's cases of complete perforation occurred in equal numbers in both sexes, and the average age of the patients was 32½ years. The small intestine (generally the ileum) was the seat of perforation in 6 and the large in 4. In 2 cases there were 2 complete perforations, and in 1 case 4. Of the perforations in the large intestine, three were in the appendix and one in the head of the cæcum. In one case the appendix had completely ulcerated off at the tip, and in another there was a perforation at its base. In tuberculous perforation of the intestine the symptoms so characteristic of perforation of the stomach or intestines in general are seldom present, and therefore the condition is not diagnosed. In 4 of the 10 cases they were fairly typical. Thus a woman, aged 33 years, suffering from pulmonary tuberculosis, was admitted without any abdominal symptoms. A week later diarrhœa began, and a fortnight after this she complained of marked abdominal pain. The abdomen was distended, rigid, and tender on the left side. On the next day she was collapsed, with the abdomen greatly distended, tympanitic, hard, and painful, and the diarrhœa was severe. On the following day her face was pinched, she was extremely weak, but was free from pain and the diarrhœa had stopped. She died that evening. The necropsy showed a perforation of the ileum and purulent peritonitis. On the other hand, the symptoms may only suggest the possibility of perforation. Thus a woman, aged 35 years, suffering from pulmonary tuberculosis, was admitted with diarrhœa. One day her temperature became subnormal, her pulse more rapid, and she lay in a state of stupor. The diarrhœa stopped, her mind became clear, but she died a few days later. The necropsy showed a perforation of the cæcum and acute peritonitis. In

another case a woman, aged 22 years, with slight diarrhœa one day complained of abdominal pain. On the next day the pain was severe and accompanied by a slight fall of temperature, but no change in the pulse-rate, which was previously high. On the eighth day after the onset of the pain she died. The necropsy showed 2 perforated ulcers at the lower part of the ileum and acute peritonitis. In 5 cases the symptoms were most indefinite; in 2 there were absolutely no abdominal symptoms, in 1 the only abdominal symptom was pain; in 1 there were pain, tenderness, and rigidity, with slight change in temperature and pulse. When it is remembered that all these symptoms may occur in cases of tuberculous ulceration of the intestines, with perhaps some localised peritonitis but without perforation, it will be realised how difficult or impossible it may be to diagnose perforation. Partial perforation is not a matter for clinical observation; it is merely observed post mortem.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

A MEETING of the Governors and General Council of King Edward's Hospital Fund was held on Dec. 11th at St. James's Palace under the chairmanship of the Speaker of the House of Commons, for the purpose of awarding grants to hospitals and kindred institutions. The treasurer reported that the amount received to date by the Fund for general purposes, less expenses, was £176,745. The Distribution Committee has apportioned £151,000 to be distributed among 105 London hospitals—£1000 more than in 1910. The chairman, in moving the adoption of the various reports and awards, read a letter of congratulation from the King, and announced with regret the resignation of Mr. F. M. Fry from the post of joint honorary secretary.

ACUTE POLIOMYELITIS AND CEREBRO-SPINAL FEVER.

THE attention of the Local Government Board has been drawn to the recent occurrence in this country of several local outbreaks of acute poliomyelitis. Some of these outbreaks, which have been chronicled in our columns, have been made the subject of detailed investigation by medical inspectors of the Board, and their reports, says Sir Horace Monro in a recent circular letter to sanitary authorities, will shortly be issued, together with a summary of the history of the disease, and an account of its pathology. Sir Horace Monro's memorandum shows that at the commencement of these outbreaks some difficulty was experienced in the diagnosis of the disease, owing to the similarity of its symptoms and those of cerebro-spinal fever. The mortality is comparatively high amongst persons attacked by either of these diseases. In cerebro-spinal fever the majority of those who survive an attack recover their normal health after a prolonged and tedious convalescence. In acute poliomyelitis, which occurs in children, and less frequently in adults, a very large proportion of the survivors are left disabled, in greater or less degree, by muscular paralysis. "It is," says the memorandum of the Permanent Secretary of the Local Government Board, "desirable, in the interest of the public health, that both diseases should be made notifiable, in order that the council and their medical officer of health may be informed as soon as possible of the occurrence of cases of these diseases. It will thus be practicable to initiate prompt inquiry into their origin and incidence and to take any precautions necessary to prevent their spread." In several districts acute poliomyelitis and cerebro-spinal fever have already been made notifiable; where this has not already been done the Board suggests that the authority should take steps at an early date to require notification. The circular is accompanied by memoranda from Dr. A. Newsholme, medical officer to the Board, on cerebro-spinal fever and acute poliomyelitis. These memoranda contain in a succinct form all the information available for the diagnosis of the conditions and the prevention of their spread.

IN addition to the Durbar Honours, which will be found in another column of this issue, the Kaisar-i-Hind Medal of the First Class has been conferred upon Dr. Herbert F. Lechmere Taylor, of the Church of Scotland Mission, Jalalpur, in the Gujrat District, Punjab, and in charge of the Jalalpur Hospital; on the Rev. John Cameron Young, M.B., C.M. Glasg., medical missionary of the Keith Falconer Mission at Sheikh Othman, Aden; and on Dr. Raghavendra Row.

WE regret to announce the death, on Dec. 11th, of Dr. Edmond Fauriel Trevelyan, of Leeds, a leading Yorkshire physician and formerly professor of therapeutics in the University of Leeds.

IN connexion with the impending reorganisation of London public health administration under a single authority, we understand that proposals are being considered by committees of the London County Council for the appointment of six whole-time permanent medical officers to carry out work relating to medical inspection and infectious diseases. The appointments are being made with a view of securing coöperation with the medical officers of health of the metropolitan borough councils. A further official will superintend the work of the new officers.

THE HEALTH OF THE NAVY FOR 1910.[1]

FOR many years, and until quite recently, the statistical reports of the health of the navy had been little but a series of dull tables of figures, with the minimum of comment to explain or make them interesting; but when Sir James Porter became Director-General the report for 1909 was enlarged, excerpts from the original journals of medical officers were again published, and the book became once more of great value to the student of naval hygiene. A further improvement is made in the number for 1910, as one of the staff at headquarters has written an article "On the History of Beriberi as it has Occurred in the Persian Gulf Squadron," an article discussing, with the fullest knowledge of all the epidemics in the last 12 years, the incidence of the disease and the theories of its origin which have been put forward in the service. Such papers are of great value and should take, in tropical medicine and geographical pathology, the place filled in relation to the public health of this country by the reports of the inspectors of the Local Government Board.

Divisions of the Naval Force.

Anyone who spends time in considering the report for 1910 will see that the naval force, as arranged in the tables, falls naturally into three groups: the Home Fleet of 50,000 men, the Home Station of 25,000, and the remainder the fleets abroad, aggregating 40,000. Of these, the Home Station shows the greatest percentage of sickness, the average loss of duty through illness being 13¼ days. We may very well find an excess of sickness in this group, as it contains both extremes of naval life; at the one end boys and new entries, at the other the older men who are not being sent abroad as they are just about to take their pensions. The smallest sick lists are shown by the great Home Fleet, whose men averaged only 8¾ days' illness in the year; the men abroad have 9¼ days on the sick list, and besides a greater chance of death than the men in the other groups. Some will be surprised to hear that statistics indicate service abroad to be healthier than service at home, and to learn that the men of the Home Fleet in the "cold and stormy home waters" show the least illness of all. Too much stress must not, however, be laid on these figures, for these are

[1] The Health of the Navy for 1910. London: Wyman and Sons. 1911. Pp. 200. Price 1s. 1d.

only crude sickness rates, uncorrected for age distribution. As death-rates vary with age, so also do sickness rates, but there is nowadays no statement in the health report of the navy about the age constitution of the various groups.

Proportional Incidence of Disease in the Royal Navy in 1910 (Ratios per 1000).

—	A Training establishment.	B Home Fleet.	C Fleets abroad.	D Home Station.	E Total force.	F Marine headquarters.
Number in group	2528	9,000	37,580	26,950	113,530	6180
Cases	1008	573	675	771	653	662
Invalids	20·9	—	—	—	15·4	—
Deaths	3·2	2·5	4·1	2·9	3·1	3·4
Sick daily	33·0	24 0	25·0	36·0	27 0	25·0
Days of service lost to each man through illness	14·0	8·8	9 3	13·3	10·0	9·2
Pneumonia	9·9	4·0	3·2	7·5	4 6	2·4
Tubercle	—	2 1	2·4	2·4	2·3	2·6
Catarrh, sore throat, tonsillitis	—	82·0	76 0	169·0	105·0	—
Rheumatic fever	46·0	7·1	7·3	12·7	8·5	1·6
Enteric fever	—	0·8	1·7	1·4	1·4	0·97
Appendicitis	—	2·3	2·9	2·2	2·5	—
Venereal diseases	—	110·0	109·0	144·0	119·0	79·0
Injuries	104·0	144·0	156·0	111·0	140·0	166·0

Column A is included in Column D. Column E is the sum of Columns B, C, and D. Column F is not included in Column E.

The report deals with a "total force" of 113,530 men amongst whom occurred 74,253 fresh cases of disease or injury, of whom 358 died and 1747 were invalided out of the service. There were, on the average, 3124 men always on the sick list, rather less than half of them sick on board their ships or at their homes on leave, and rather more than half of them in the hospitals (515 daily average at Haslar, 435 at Plymouth, 387 at Chatham). The "total force" as stated above does not, curiously enough, account for all the men, for an extra group of 6180 "marines at headquarters," not included with the others, has a little table all to itself at p. 149.

Improved Health of the Fleet.

The improvement which is being made in the health of the fleet by diffusion of knowledge of sanitation, the building of better ships, the better selection of recruits, and by modern advances in the treatment of disease can be well shown by comparing the figures for 1910 with those of 10 and 20 years ago.

Year.	Total force.	Per 1000. Cases.	Invalids.	Dead.	Sick daily.	Days of service lost by each man by illness.	Days under treatment. Each case.
1890	53,350	1063	26·18	8·54	42·3	15·5	14·5
1900	96,830	882	35·83	7·27	37 6	13·7	15·5
1910	113,530	653	15·38	3·15	27·5	10·0	15·3

We can see from the figures that hygiene must be improving and skill in treatment increasing. There is definite evidence of improving surgical skill among the medical officers of the navy and of increased confidence by the men in their skill, for in 1900, 73 operations are reported for radical cure of hernia, and 532 were done in 1910; further, in 1900, 239 men were invalided for hernia, of whom "the greater number," at least 120, had refused operation, but in 1910, of the 82 who were all that were invalided for this disorder only 31 had refused operation.

Incidence of Different Diseases.

The total sickness is much the same as in 1909, but we notice that pneumonia has increased in the Home Fleet, where there were 196 cases (30 per cent. increase), 2 invalids and 19 deaths. No explanation is offered of the greater prevalence. We observe also that invalidings in the first year of service have increased very materially (p. 15) from 166 to 286. The chief increases were: nervous diseases, 39 (against 17 in 1909); diseases of the ear, 37 (against 17); diseases of the circulatory system, 87 (against 20). Rheumatic fever, 7 (against 22), shows a decrease; it is uncertain if this is a real decrease or due to transference of cases with heart disease to the class of circulatory diseases. So considerable an alteration in the rate of invaliding should surely, if noticed, have evoked some explanation. Further, we should have liked to hear why there is such excess of morbidity in the training establishments (p. 150). The pneumonia rate is double, the rheumatic fever rate five times, those obtaining in the navy generally. No account of the health of the cadets at Osborne or Dartmouth, of which so many people have been asking questions, can we find anywhere. Probably it will be included in the report for 1911.

A considerable epidemic of mumps is reported from Australia; 84 cases occurred in one ship of 425 men. There was no special prevalence of influenza in any one ship this year. A very large number of the cases of influenza occurred among men at home on leave; it is questioned if the diagnosis was always correct (p. 20); all 4 deaths occurred in men away on leave.

Enteric and Mediterranean Fever.

The cause most frequently assigned for enteric fever is the eating of infected shell-fish. One fleet-surgeon (R. D. Jameson) traced a case to a shop in a distant town and found that shop already suspected by the medical officer of health there. H.M.S. *Swiftsure* and H.M.S. *Scylla* still went on having cases of enteric fever. H.M.S. *Swiftsure* had 12 cases last year and 9 in January, 1910; 2 more developed in August and 2 in November. No cause, not even drinking shore water or eating green vegetables that may have been infected, is suggested, but the report says: "It is somewhat suggestive that a ship so badly infected should continue to contribute cases," which seems to indicate that if cases go on appearing this year in the ship it may be officially declared infected, and then something will be done. There is talk of a carrier perhaps being the cause of the infections on H.M.S. *Scylla*, but it is not stated whether measures have been taken to discover him clinically or bacteriologically. No cases of paratyphoid fever are mentioned.

One officer contracted Mediterranean fever in China, having drunk raw goats' milk when passing through Malta. Thirty men are daily doing drill and otherwise learning their work in the Mediterranean Fleet who, but for the work of Sir David Bruce and sanitary regulations founded upon it, would be aching in hospital instead.

Pneumonia.—Malarial Fever.—Tuberculosis.

Pneumonia (519 cases) has increased; cases come in groups from individual ships—7 from *Vanguard* at Berehaven between April 23rd and May 10th. No remark is made about the increase. It would be well if whenever a case occurred the cubic content of the apartment and the number of men sleeping in it could be noted, and with that the area of inlet and outlet ventilation. These could be tabulated later, and in that way much would be learned. Pneumonia in ships is so often a disease of overcrowding that when a case is reported and overcrowding is not definitely disproved at once, it is hard not to suspect that it exists. 321 cases of malarial fevers occurred in the East Indies, but no word is said of the methods of prevention that were or might have been taken, and of their proportional success. Of 611 cases in the service only two died.

260 cases (2·44 per 1000) of tuberculosis occurred, of whom 205 were invalided and 26 died. Marines seem to suffer most. 65 are daily on the sick list through tubercle, and 231 were lost by it to the navy in 1910. The real totals are probably a trifle larger than the figures, as cases of hæmoptysis, broncho-pneumonia, and phthisis are still reported under other headings. 208 were lung cases, 12 in joints, 7 in glands, 5 genito-urinary, and 2 in the skin. The greatest number of cases reported from any individual ship was 5.

Venereal Diseases.

Under venereal diseases there were 13,402 (118 03) cases, 148 (1·29 per 1000) invalidings, and 6 (0·22) deaths. One-third of the sickness of the service is shown as due to venereal disease, but some cases of locomotor ataxia and

general paralysis of the insane are reported merely as nervous diseases, and there should also appear under this heading some of the cases of aneurysm, stricture, and suicide. Three cases of syphilis insontium are mentioned (pp. 42, 76, and 88). Twelve cases of venereal disease occurred for every 100 men, and roughly, 2 were chancroid, 1 primary syphilis, 3 were secondary syphilis, and 6 were gonorrhœa. These diseases are apparently lessening. About 1890 there were 6 cases of sores, 2 of secondary syphilis, and 8 of gonorrhœa, 16 cases in all, to 100 men. Venereal disease has thus lessened in 20 years, 3000 cases being saved in a year—a vast improvement.

Rheumatic Fever.—Parasitic Diseases.

In rheumatic fever (969 cases) there was a considerable increase, but it appears that ordinary muscular rheumatism is this year counted with rheumatic fever. The disease is specially prevalent on the Home Station, particularly in the training establishments. It is suggested that this disease (p. 8) is due to climate and the severity of service at home, but more cases are reported from abroad than from the Home Fleet. Of parasitic diseases, there were 3135 cases of scabies in 1910, a reduction of 429 cases, or 2·9 per cent. In the Japanese navy of 40,000 men there were, in 1907, 337 cases reported, or 8 per 1000. In the American navy of 57,000 men there were, in 1909–10, 316 cases; and in the German navy of 50,000 men (1908–09) there were 570 cases of infection by animal and vegetable parasites.

Beri-beri.—Defective Teeth.—Non-venereal Bubo.

Much attention is being paid in the navy to beri-beri, which has given lately a good deal of trouble in the Persian Gulf. In 1910 it attacked 22 Europeans. A full clinical account of these cases would be of interest. Two papers on beri-beri are in the appendix: one is by Fleet-Surgeon R. C. Munday (p. 179) dealing with prevention and treatment. He recommends the mungo or katjang-idjoe bean (phaseolus radiatus). We have recently mentioned its value in this connexion.[2] The number invalided in 1910 for defective teeth is only seven; in 1909 the navy lost 122 from this cause, but unfortunately no explanation of the improvement is given. There were 327 cases of non-venereal bubo, an important disease, for it occurs on the China and Cape of Good Hope stations, and is reported to be related to plague. A paper in the appendix to the report for 1911 discussing the pathology and treatment of this disorder would be very welcome.

Local Diseases.

As to local diseases, the highest death-rate and the highest invaliding rate are associated with diseases of the circulation. How many of these are due to rheumatic fever we cannot say completely, but it accounted for 30 per cent. of the 262 who were invalided for organic heart disease. The largest daily loss of service is from diseases of the digestive system; half of these cases are sore-throat and tonsillitis. There were 280 cases of appendicitis, which seems to be more prevalent in the American and German navies, but less frequent in the Japanese.

Great Improvement in Diseases of the Lungs.

It is a little difficult to compare the loss from respiratory diseases and from tubercle now and formerly, as cases have been sometimes returned under one head and sometimes under another. If, however, we add together the respiratory and tuberculous figures for 1890 and those for respiratory and tuberculous disease and for pneumonia in 1910, we shall get a very fair idea of the improvement which has occurred. The figures are:—

Respiratory and tuberculous diseases.	1890.		1910.	
Cases per 1000	82		74·5	
Invalided per 1000	4·1 } waste		2·3 }	waste 2·9
Deaths per 1000	1·6 }	5·7	0·6 }	

They show that the waste of the service (deaths and invalids) has been halved in 20 years, an enormous advance.

Accidents.

We must not neglect to mention a suggestive note by Fleet-Surgeon E. B. Pickthorn on the influence of care and forethought in the prevention of accidents (p. 47). That principle applies in exactly the same way to the prevention of disease, as medical officers must show to the executive officers with whom they serve.

Compressed Air Illness in Diver.

The most striking story in the appendix is that of the diver who came up too quickly from a depth of 16 fathoms and was consequently attacked with cramp, headache, and nausea. Fleet-Surgeon R. S. Bernard got him quickly back into his diving dress and sent him down immediately to 12 fathoms to get him again under pressure. The man was now 72 feet down below his medical adviser, was all alone, and could only be communicated with by telephone—an anxious position for both patient and physician. In ten minutes the patient began to improve and was allowed to make his way slowly to the surface, and when he reached the top at last in 40 minutes he was found to have recovered. The other papers in the appendix are also of great interest.

[2] THE LANCET, Dec. 2nd, 1911, p. 1570.

THE LONDON COUNTY COUNCIL AND THE CARE OF THE FEEBLE-MINDED AND INSANE.

AN interesting debate took place at the meeting of the London County Council on Dec. 5th with regard to questions of recurrent insanity and the care and control of the feeble-minded.

Report on Deputation to the Home Secretary.

The General Purposes Committee reported that a deputation from the Council had waited upon the Home Secretary to urge that legislation should be promoted to deal with the whole question of the care and control of the feeble-minded, and particularly to confer on the Council authority to make provision for persons lacking in moral sense.[1]

The Home Secretary, in his reply to the deputation, said that both he and the President of the Board of Education were deeply interested in the subject and in securing a remedy very much on the lines asked for by the Council. He had in draft an Inebriates Bill and also the heads of a Bill for dealing with the feeble-minded, both of which he trusted would become law next session. Mr. McKenna added that the last-named Bill would be compulsory and not adoptive, and provision would be made for the care, after the age of 16, of feeble-minded children and for the care of imbeciles. Further, the Home Office was in entire agreement with the Council's contention for the establishment of a central authority. As regards the question of the treatment of inebriates, he foreshadowed legislation whereby magistrates would be enabled in every case to commit a habitual inebriate to receive reformatory treatment, and he indicated that assistance from the Treasury might be expected towards the establishment and maintenance of reformatories. As regards the question of the care and treatment of lunatics in their relation to the feeble-minded, the Home Secretary pointed out that the establishment of a central authority would trench upon, and he hoped relieve, the burden of dealing with lunatics.

The President of the Board of Education (Mr. Pease) addressed the deputation on the question so far as it related to the education service, and referred to the necessity of making compulsory the operation of the Elementary Education (Defective and Epileptic Children) Act, 1899, and of educating the feeble-minded children in every district, thus reducing the number of adult cases to be dealt with.

This report was received without comment.

Recurrent Insanity and the Propagation of the Unfit.

A discussion, however, took place subsequently on the report of the Asylums Committee already mentioned in THE LANCET.[2] This report had reference to a lunatic who had been in and out of Banstead and other asylums 26 times and had had 13 children, two of whom had shown signs of insanity. In giving the details the committee merely said: "It seems a striking illustration of the need for legislation to prevent the increase of the unfit," and made no definite recommendation.

Mr. A. O. GOODRICH, chairman of the Asylums Committee, said this was one of the cases of recurrent insanity in regard

[1] THE LANCET, April 29th, 1911, p. 1164, and Dec. 10th, 1910, p. 1717.
[2] THE LANCET, Oct. 28th, 1911, p. 1222.

to which the committee was anxious to do something practical. The problem of constant readmissions was causing those responsible for the London County Asylums a great deal of anxiety. At present, although the committee very well knew that in many cases there was every probability of a patient returning, no power existed by which they could detain a patient who had recovered. Members of the Council might be astonished to know that between 1885 and 1910 no less than 29 per cent. of the patients discharged were readmitted into London County asylums. He would be asked what practical suggestion he had to make; this was, however, a very difficult matter, and therefore the committee had not made a definite recommendation. There were various ways of dealing with the problem. One suggestion was segregation; in this direction the Eugenics Society was doing noble and good work, and was promoting a Bill in Parliament to deal with the question; he hoped the Council would support them. A method was by colonisation; a number of the insane of one sex would be put on an island and kept there practically for life. Another method was by means of surgical operation—of course, under proper safeguards. They knew on the excellent authority of Dr. F. W. Mott the hereditary character of mental deficiency. Nearly all the patients of this class had relatives who were, or had been, insane. He believed the whole of the committee was united in thinking that some form of State control should be exercised in cases of recurrent insanity.

Mr. EDWARD SMITH thought that on this important subject the Asylums Committee should have presented a more exhaustive report and have made some definite suggestion. Mr. Goodrich touched on very dangerous ground when he suggested that because a young woman became insane and entered and left an asylum three or four times she should be taken from her family and all her associations and placed on a remote island. He had known cases which had become permanently cured after three or four entries into an asylum.

Sir JOHN MCDOUGALL: What about the next generation?

Mr. SMITH said that he was content to deal with the present generation. This subject ought not to be discussed by the County Council, but by another body with power to take definite action.

Sir JOHN MCDOUGALL welcomed the report as calling public attention to a serious peril that lay before the nation. It required very careful consideration before any practical suggestion could be made. He mentioned a case of a woman who had been in an asylum before she was married. She had had five children, and one daughter, aged 17, was in the same asylum. The problem urgently required attention. Dr. Mott was making very strenuous inquiries and obtaining the most exhaustive statistics. At present there was no power to prevent the propagation of the unfit.

Mr. H. H. GORDON said that no one reading the report of the Royal Commission on the Feeble-minded could fail to be struck by the number of cases of women coming to workhouses year after year to give birth to incapable and degenerate children. It was not kindness to allow women to go out into the world and be subject to temptation, which owing to their feeble-mindedness they were unable to resist. It was not fair to them and the rest of the community to allow them to give birth to children who invariably proved to be feeble-minded. They deplored a falling birth-rate among the physically fit, but took no steps to try to prevent the propagation of the unfit. As to sterilisation, he was told that the religious conscience of the community would be against such a course. If this was considered the only effective method of dealing with the problem, then the religious community must be asked to say how else it was to be solved. The present state of things could not go on indefinitely, and he trusted the Asylums Committee would bring forward case after case of the kind presented in this report, and that they would be published widely all over the kingdom in order that public opinion might be educated.

Mr. E. G. EASTON said that Dr. Mott had such cases by the score. After referring to the growing cost of asylums, Mr. Easton declared that the Asylums Committee could not have taken more definite action because the medical profession hesitated to express itself as strongly as many laymen desired.

Mr. H. C. THOMAS quoted a medical authority as saying that of the inmates of asylums 32 per cent. were there through worry alone and 26 per cent. through excessive alcoholism, largely due to the conditions under which they lived. The following remedies had been suggested:—A living wage; insurance against sickness and unemployment and provision for old age; the abolition of slums and overcrowded areas; and the encouragement of the family and family life. It was encouraging to think that such a considerable proportion of the insanity they had to deplore was due to removeable causes, and it was to be hoped that the next few years would show a great fall in the number of asylum inmates.

Mr. E. W. HOBSON said that, although the Asylums Committee had amassed more information on this subject than any other dozen authorities, yet it only gave the Council a mere recital of facts. He hoped the committee would make definite use of its invaluable reports by medical experts, for the information of the people of England in dealing with this most serious question.

Mr. C. JESSON mentioned a case of a young man being anxious to marry a girl—a moral imbecile—who was just leaving an asylum. In spite of all endeavours to dissuade him the man married the girl, and no one could interfere in the matter, as the girl was not at that moment insane.

Mr. H. W. ROWE, a former chairman of the Asylums Committee, declared that no one was willing to bear the onus of the unpopularity of such a proposal as the steriltsation of the insane.

Mr. J. W. GILBERT declared strong opposition to dealing with recurrent insanity by sterilisation.

Notice of Motion.

In order to secure a definite result from the debate Mr. Walter Reynolds has since given notice of the following motion:—

That in order to enable the Council to decide what action should be taken for the prevention of lunacy, especially so far as it is due to hereditary transmission by persons known to be of unsound mind and is to that extent preventable, it be an instruction to the Asylums Committee to submit a full report on the subject of the causes of lunacy, particularly the hereditary causes, with particulars of cases which have come under the observation of the committee of the hereditary transmission of insanity.

MEDICAL MEN AND MUNICIPAL HONOURS.

WE print below brief notes of the medical and municipal careers of the members of the profession who have been elected or re-elected to the mayoral chair. We have dealt already with the appointment of Sir Thomas Crosby to the office of Chief Magistrate of the City of London, and with the relation of medical men to an active municipal life.

Barnstaple.—Mr. John R. Harper, M.R.C.S. Eng., L.R.C.P. Lond., was educated at St. Thomas's Hospital, where he held several house appointments. He is surgeon to the North Devon Infirmary, medical officer of health for Barnstaple rural district, and up to his appointment as mayor of Barnstaple held the posts of medical officer of health of the borough and school medical officer. These two appointments he resigned upon being made mayor. He is a major in the Royal Army Medical Corps, Territorial Force.

Bolton.—Mr. J. Young, M.R.C.S. Eng., L.R.C.P. Lond., who was educated at the Owens College, has been a member of the Bolton town council for eight years and an alderman for four years. He is president of the Bolton Medical Ethical Society and past president of the Bolton Medical Society, a member of the Court of Governors of Victoria University, and chairman of council of the Association of Technical Institutions. He is also a member of the Textile Institute and other educational associations, as well as a governor of several secondary schools.

Congleton.—Mr. W. I. Fern, J.P., L.R.C.P. Irel., L.R.C.S. Edin., was born at Hurdsfield, Macclesfield. He was educated primarily at Christ Church School, Macclesfield, and electing medicine as his profession subsequently went to the Owens College, Manchester, and studied at the Manchester Royal Infirmary. Nine years ago he was returned a member of the town council of Congleton; he is a member of the finance committee and chairman of the watch committee. In his medical capacity he is public vaccinator for Congleton.

Exeter.—Mr. C. J. Vlieland, M.D. Durh., M.R.C.S. Eng.,

L.S.A., after serving as house surgeon at the Kent and Canterbury Hospital in 1879 and at the Hertford General Infirmary in the following year, took up his residence at Exeter in 1882, where he entered into partnership with the late Dr. Mark Farrant. Ten years later he dissolved partnership, but continued in practice. He has been medical officer of health of Exeter since 1882, first under the local board of St. Thomas, subsequently under the urban district council, and afterwards, on the annexation of St. Thomas by the city of Exeter, he was appointed assistant medical officer of health for No. 3 (St. Thomas) District. The offer of the mayoralty for the ensuing year, which he accepted, came as a complete surprise to him, and appears to have met with unanimous approval. He has resigned his appointment as medical officer of health during his mayoralty only.

Faversham.—Mr. S. R. Alexander, M.D. Lond., M.R.C.S. Eng., L.S.A. (re-elected), is an old student of London University and Guy's Hospital. He has been chairman of the governors of the Faversham Grammar School for several years, is a trustee of public charities, a governor of Wreight's and Gibbs's Schools, and represents the University of London on the higher education committee. His election to the mayoral chair last year is believed to be a unique event in the history of the borough, as he had been previously unconnected with the corporation. As Mayor of Faversham he is a Baron of the Cinque Ports, and in that office attended the Coronation of the King in Westminster Abbey. He married in 1890 a daughter of the late Mr. Alfred George Schiff.

Hertford.—Mr. J. Burnett Smith, M.B., C.M. Edin., L.R.C.P. & S. Edin., L.F.P.S.Glasg., is medical officer for the Herts and Ware isolation hospital and the Herts workhouse and workhouse infirmary. He is medical officer and public vaccinator for the No. 1 District of the Hertford Union, and was formerly house surgeon at the Royal Infirmary, Glasgow, and at the Hertford General Infirmary.

Hartlepool.—Mr. W. S. Gibb, M.B., C.M. Edin. (re-elected), is an honorary physician to the Hartlepools Hospital.

Leamington.—Mr. Harold Mason, M.B. Lond., M.R.C.S. Eng., L.R.C.P. Lond., L.S.A. (re-elected), was educated at Leamington College and received his medical training at Birmingham. He qualified in 1890 and proceeded to the M.B. Lond. in the following year. After holding residential posts at the General Hospital, Birmingham, he became medical officer to the Leamington Provident Dispensary, and has been in active practice for 19 years. He has written one or two papers on the etiology of cancer. In 1898 he successfully contested the South-East Ward of Leamington and was returned unopposed in 1901. In 1904 and in 1907 he was again elected, and last year was appointed mayor, which honour has again been conferred upon him. For ten years previous to his mayoralty he was chairman of the health committee.

Lewes.—Mr. H. Stott, M.R.C.S. Eng., L.R.C.P. Lond., L.S.A., belongs to a medical family which for seven generations has been able to count a medical man among its members. For 16 years Mr. Stott was in private practice at Friern Barnet, and held several public appointments, afterwards removing to Lewes, where he has rendered great service to East Sussex as medical officer of health of the combined districts. He is a Fellow of the Society of Medical Officers of Health and secretary of the Brighton and Sussex Medico-Chirurgical Society. In the subject of national defence Mr. Stott takes a great interest, and was formerly a commanding officer to the Cinque Ports Rifles. He is now a Major in the Special Sanitary Service (Territorials). It is worthy of note that after being appointed Mayor Mr. Stott was elected a member of the Council.

Macclesfield.—Mr. C. A. Bradley, M.R.C.S. Eng., was educated at the Owens College, Manchester, and qualified in 1877. At one time he was visiting surgeon to the Macclesfield General Infirmary.

Newport (Mon.).—Mr. J. McGinn, F.R.C.S. Irel., L.R.C.P. & S. Edin., L.F.P.S. Glasg., was born at Omagh, County Tyrone, in 1862, and was educated at the Christian Brothers' Schools and by private tuition. He received his professional education at the Royal College of Surgeons, Dublin, where he obtained a Fellowship in 1900. After qualifying in 1887 he served a term at the Tyrone County Infirmary as assistant surgeon and then proceeded to Aberdare, where he assisted at the Cottage Hospital and the Aberdare works and collieries for nearly two years. He went to Newport in 1890, when he succeeded to the practice of the late Dr. Ready. He was first elected to the Newport council in 1897 as member for the central ward, which he has since represented with a short interruption, when he was defeated in the newly constituted Crindau ward, which he selected at the redivision of the borough. He is deputy chairman of the health committee and chairman of the hospital sub-committee, and a member of the education, asylum, and parks committee. He married in 1902 a daughter of the late Mr. A. J. Murphy, an old inhabitant of Newport.

Montgomery.—Mr. Nicholas Watson Fairles-Humphreys, M.R.C.S. Eng., L.S.A. (re-elected), was born in 1837 and studied medicine at St. Bartholomew's Hospital. In 1885 he was elected alderman for the borough of Montgomery and has been 13 times mayor. He is a justice of the peace for the county of Montgomery, was high sheriff in 1882-83, and has been a county alderman since 1889. His grandfather, Nicholas Fairles, justice of the peace for the county of Durham, was the originator of the lifeboat movement, and chairman of the first committee.

Pwllheli.—Owen Wynne Griffith, L.R.C.P. & S. Edin., was educated at Guy's Hospital, London, qualified in 1878, and has practised for over 32 years in the "Lleyn" Peninsula, Carnarvonshire. He was first elected a member of the town council of the borough of Pwllheli in 1891 and was returned unopposed in 1894. He was elected alderman in 1896, 1902, and 1908, and was mayor in 1899-1900. He has served on the Carnarvonshire county council for 16 years, and has occupied an aldermanic chair. His name and efforts have for a lengthy period been associated with county, country, and corporate institutions, whilst his influence is a prominent factor in public, private, and philanthropic benefactions.

Saffron Walden.—Mr. J. P. Atkinson, M.D. Glasg., L.R.C.P. Lond., L.R.C.S. Edin. (re-elected), was born in 1838. After serving a term of pupilage with Mr. Little, Mr. Young, and Mr. Adams, of Boston, he proceeded to Glasgow University, where he received his medical education, and graduated as M.D. with honours in 1863, having previously passed the examination for the diploma of the Royal College of Surgeons of Edinburgh. In the same year he took the L.R.C.P. Lond. Subsequently he settled at Bampton, Oxon., but removed in 1881 to Saffron Walden, and finally retired from practice in 1908. He entered the town council of the borough of Saffron Walden in 1888 and in 1891 was elected mayor, being re-elected in the following year. He was again appointed in 1900 and re-elected in 1901, and was mayor at the time of the Coronation of the late King Edward VII. and received the Coronation medal. This year he has been elected mayor for the sixth time. Dr. Atkinson joined the medical staff of the 3rd V.B. the Suffolk Regiment, received the V.D. in 1904, and retired with the rank of surgeon-colonel in 1905. He has represented the town council on the joint isolation hospital board, of which he has been chairman since its incorporation in 1903, is a member of the Essex County Territorial Force Association, and has represented the borough on the Essex county council, and also on the county association recently formed for combating consumption.

Wallasey.—Mr. John Oldershaw, J.P., M.D. Brux., L.R.C.P. Irel., L.R.C.P. & S. Edin., L.F.P.S. Glasg., is the second son of the late Mr. Isaac G. Oldershaw, of Lenton Hall. He was born at Derby, and was educated at Prescot Grammar School and at Cambridge, Edinburgh, and Brussels. His family has long been connected with the learned professions, numbering Dr. John Oldershaw, of Starton, who died in 1807, being a noted physician; and the Venerable Archdeacon Oldershaw, who died in 1847 (the son of a Leicester physician), a zealous dignitary of the Church. Dr. Oldershaw has always taken the greatest interest in local matters, and especially in the question of education, and to his influence must be attributed the building of many of the schools in Wallasey, which was the first town to possess a higher elementary school. Deputations not only from the furthermost parts of England, but from the Continent, have come over to see the schools and to profit by the methods employed in teaching. He entered the town council in 1897, and has served as chairman of several of the committees. Dr. Oldershaw had the honour of being chairman of the council during the year of the Coronation of King Edward VII. He married the only daughter of the late Mr. John Holbrook, of Rolleston, Staffordshire.

Warrington.—Mr. G. W. Joseph, M.D. Durh., L.R.C.P. Irel., M.R.C.S. Eng., L.S.A. (re-elected), was born at Liverpool on Nov. 29th, 1850. He is the son of Mr. Neild Joseph, chemist, of that city, and was educated at Kirkbean School, near Dumfries, and at Liverpool Institute. He studied medicine at Liverpool Royal Infirmary School of Medicine, and University College, Liverpool, and after matriculating at the University of Durham he qualified in 1873, proceeding later to the Durham degree. He went to Warrington in 1874 as house surgeon to the infirmary, and for seven years was medical officer of health of the borough, and was also first public analyst for the borough. For 30 years he was honorary surgeon to the infirmary, and is now honorary consulting surgeon to that institution. He entered the Warrington town council in May, 1905, and has served on the health and other committees. He is chairman of the watch committee, and deputy chairman of street improvement committees, and takes a great interest in sanitary and social reform. In 1909 he was appointed a justice of the peace for the borough.

Wimbledon.—Surgeon-Major E. L. McSheehy, A.M.D. (retired), M.D., M.Ch.R.U.I., F.R.C.S. Irel., who is a justice of the peace for the county of Surrey, was educated at Queen's College, Cork, and at Paris. He entered the medical department of the army in 1857 and retired from the service 20 years later. He has always taken an active interest in the municipal affairs of Wimbledon and is a much respected member of the borough.

MEDICINE AND THE LAW.

A Rink and its Neighbours.

IN the case of Page and others *v.* Watt and others, tried by Mr. Justice Darling without a jury, damages and an injunction were claimed by persons residing in the neighbourhood of a roller-skating rink against its proprietors, a nuisance being alleged arising out of the noises made by the skating, a mechanical organ, varied by a band, a megaphone used for making announcements to the skaters, and a siren. After witnesses had been called on both sides his lordship awarded as damages £20 to a plaintiff who owned certain houses affected, £10 to the former occupier of one of them, and £20 to the occupier of another. An injunction was refused. The result of this case, with that of the recent action referred to in THE LANCET of Nov. 25th, p. 1505, in which noises arising out of the Exhibition at Earl's Court were complained of, should tend to make caterers for the public more careful before they open places of amusement to prevent them as far as possible from interfering with the comfort and health of those who have no pecuniary interest in them.

Hebert v. *The Royal Society of Medicine.*

The Court of Appeal recently had before it an appeal from the decision of Mr. Justice Darling in a case in which the question at issue was whether the plaintiff, Dr. P. Hebert, was entitled to describe himself as a member of the Royal Society of Medicine. He had been so described in the advertisement of a book of which he was the author, and the secretary of the society had written to the publishers to the effect that he was wrongly so described. His claim to membership of the Royal Society of Medicine was based upon membership of the Gynæcological Society, coupled with the alleged sending of a postcard to the former society intimating his desire and intention of joining it. Under the Charter and by-laws of the defendant society the plaintiff claimed to be entitled to acquire membership thus, and that he was, in fact, a member of the Royal Society of Medicine. At the conclusion of the trial Mr. Justice Darling said that he was not satisfied by the plaintiff's evidence that he had communicated his desire to be admitted to membership of the Royal Society of Medicine in the manner described, and intimated that this finding of fact would be a decision in favour of the society in respect of the claim of membership and also of a pending action for libel in connexion with the denial of the plaintiff's right to describe himself as a member of the defendant society. The Court of Appeal declined to interfere with Mr. Justice Darling's judgment, and having dismissed the plaintiff's appeal informed counsel for the appellant that their decision and that of Mr. Justice Darling rendered the whole matter *res judicata*—that is to say, the plaintiff would be precluded from proceeding with an action for libel (or any other action) which would raise questions of fact already determined.

Petty Frauds upon Medical Practitioners.

Claude Hamilton, who described himself as a surgeon but refused to give an address, was sentenced by Mr. Chapman at the Tower Bridge police court recently, under the Prevention of Crimes Act, Section 7, to 12 months' imprisonment after proof that he had obtained, or attempted to obtain, by fraud, various small sums of money. An attempt to obtain money had been made upon Dr. R. Larkin, divisional surgeon of police residing in the Borough, and whisky and milk had been obtained from Dr. Helen Gordon Clark. In both these cases the prisoner said that he was a medical man from Australia and that he had been robbed and pretended that he was in a state of collapse. He was also charged with obaining 2*s.* 6*d.* from the Rev. R. Doran, with the variation that in that instance he stated that he was from Ireland. Fourteen previous convictions and many complaints against him were proved.

200 Bogus Claims for Accidents.

Ernest Pendrigh, 37 years of age, pleaded guilty at the Old Bailey recently to three counts of an indictment charging him with obtaining money by false pretences from tradesmen. His pretence consisted in falling down and claiming to have been injured through the negligence of the persons whom he made his victims, and during three years it was estimated that about 200 such claims had been successfully made by him with the assistance of a confederate. The prisoner suffered from a malformed right wrist, which assisted him in extracting money as supposed compensation. He was arrested through playing the same trick upon two butchers in the same morning, alleging that he had fallen upon pieces of fat outside their shops, and the fact that both at once sought the assistance of the Incorporated Society of Meat Traders led to the detection of the fraud. A man alleged to be his confederate accompanied the prisoner on the occasions in question, making notes on his behalf of the incident with particulars of the name and address of the person from whom the money was to be obtained. Pendrigh was sentenced to 18 months' hard labour. It will be noted that Pendrigh's success was due to his victims paying what perhaps seemed to them a modest compensation in preference to fighting his claim. An action would have required medical evidence as to the existence and cause of the alleged injuries, and could hardly have been repeated with safety in the same court.

ASYLUM REPORTS.

Annual Report of the Glamorgan County Lunatic Asylum for the Year 1910.—The daily average number resident at this asylum was 1652. There were admitted 338 patients. Of these, 142 males and 100 females were first attack cases and direct admissions. Cases of the confusional and demented type increased from 21 in the previous year to 44, while cases of melancholia have decreased from 91 to 59. In 41·5 per cent. of the admissions there existed an inherited predisposition to insanity, allied neuroses, or alcoholism, the proportion being 68·6 per cent. insanity and other neuroses, and 31·3 per cent. alcoholism. The chief exciting causes were mental stress 15·7 per cent., and alcohol 14·5 per cent. 132 patients were discharged, the recovery rate calculated on the total admissions being 27·8 per cent. and on the direct admissions 28·5 per cent. The deaths numbered 160, the percentage to the daily average numbers on the registers being 9·6. Post-mortem examinations were held in 105 instances, the most frequent causes of death being tuberculous disease 20 per cent., general paralysis of the insane 14 per cent., and senile decay 10 per cent. The Commissioners in Lunacy in their report dated Jan. 25th, 1910, write disparagingly of the dinner they saw served on the occasion of their visit. "The plates were cold, a considerable percentage of the potatoes were unsound, and although the portions served out to the men were for the most part sufficient, this was certainly not so in regard to the women. The portions set apart for the various tables were in no way properly divided, but wholly apart

from this, some of the meat was such as, though possibly most suitable for soup or stock, should never have been issued as table meat, consisting as it did of gristle, bone, and fat." The Commissioners trust that immediate and active attention may be given by the committee to this matter. It appears that this is not the first occasion that the Commissioners have had occasion to remark on the character of the diet at this asylum.

Annual Report of the Stirling District Asylum for the Year ending May 14th, 1911.—The average number of patients resident at this asylum during the year was 730. The admissions numbered 219. Forty-eight of those admitted had been under treatment before, but a considerable number of these were patients who had been previously discharged as unrecovered and removed to the care of their relatives or boarded out under the guardianship of strangers. In some cases the patients were returned to the asylum owing to the death of the guardian and in others on account of bodily illness or infirmity. The age of those admitted varied from 14 to 79; the largest number of males admitted were from 25 to 30 years of age and the largest number of females from 30 to 35 years of age. Only 18 of those admitted were in average bodily health. In 152 patients the health was in poor condition and 49 patients were admitted in an exhausted state. An inherited predisposition to insanity was found in 30 per cent. of those admitted. In 15 per cent. the mental breakdown was attributed to alcoholic excess, and in 21 cases insanity was the result of general paralysis and other gross forms of brain disease. One hundred and twenty-five patients were discharged during the year, and of this number 75 were recovered, giving a recovery rate calculated on the admissions of 34 per cent. for both sexes. A lowered recovery rate has been the general experience throughout the Scottish asylums of recent years. This is probably mainly to be accounted for by the accumulation in asylums of chronic incurable cases, and in part also to the present-day system of treating acute cases of mental disease in the observation wards of the large parochial hospitals. The deaths during the year numbered 76, the death-rate calculated on the average number resident being 10·2. The mean age at death was 50. Seven patients who had died had been resident in the asylum for over 20 years. Post-mortem examinations were held in 84 per cent. of the deaths. Dr. Robert B. Campbell, medical superintendent, has no doubt that the modern method of keeping the inmates of the institution as much as possible in the open air is an important factor in promoting the comfort and health of the patients. The recently admitted patients are treated in bed in the verandahs in connexion with the hospitals and the small sanatorium verandahs also have their accommodation fully taxed.

Annual Report of the Inverness District Asylum for Year ending May 15th, 1911.—The average number of persons resident at this asylum during the year was 691. The admissions during the year numbered 162, representing 159 persons, there having been two males and one female admitted twice during the year. Of the total number of patients admitted 45 had previously been under asylum treatment at this institution. Of the 45 readmissions 29 were admitted for the second time, 6 for the third time, 4 for the fourth time, 2 females for the fifth time, 1 male for the seventh time, 1 male and 1 female for the eighth time, and 1 female for the ninth time. The ages of those admitted varied from 16–90. Eighty-two of the admissions were cases of melancholia and 42 were cases of mania. As a result of the recent Census it appears that though there has been a decrease in the total population of the councils included in the lunacy district, there has not been any corresponding decrease in the admission rate of patients to the asylum. Dr. T. C. Mackenzie, the medical superintendent, considers it possible that a decrease in the general population of the district may mean for some time at any rate an increase in the population of the asylum. It may prove to be the case that aged persons, who have remained behind in their homes, while their descendants have left the country, may require to be sent to the asylum not so much because they are mentally afflicted as because there is no one at home to look after them in their old age and infirmity. Among the probable causes of insanity in the patients admitted, a hereditary or family predisposition to insanity existed in 71 of the 162 cases, whilst senility and alcoholism were amongst the assigned causes in 22 and 25 cases respectively. One hundred and fourteen patients were discharged during the year. Of this number, 71 were discharged recovered, giving a recovery-rate calculated on the admissions of 44·4 per cent. for both sexes. The number of deaths during the year was 45, the death-rate calculated on the average number resident being 6·5. Fifteen of the deaths were due to pulmonary tuberculosis and eight to senile decay. Post-mortem examinations were held in 38 out of the 45 cases. The mean age at death for male patients was 53·8 and for female patients 61·2, giving a mean age at the death of both sexes of 57·5.

Annual Report of the County Borough of West Ham Lunatic Asylum for 1910.—The total admissions to this asylum during the year were 248, of whom 106 were males and 142 females. Forty-three of the cases admitted were re-admissions and 20 were transfers. Forty-six of the admissions suffered from forms of mania and 67 from melancholia, 37 were cases of dementia, 31 of general paralysis, and 16 of epilepsy. Of the direct admissions 69 cases had a history of hereditary insanity or epilepsy, and 14 others of hereditary alcoholism, giving a total percentage of 36. It appears that of 1869 cases admitted during the nine years, 1902 to 1910 inclusive, more than 53 per cent. had a hereditary history of insanity or were congenitally defective. Of the exciting causes alcoholic excess was ascertained in 37 cases and mental stress in 25 cases. One hundred and sixty-eight patients were discharged, and of these 66 were discharged recovered, giving a percentage of 23·94 on the direct admissions. These are comparatively low figures and are due to the hopelessly incurable character of the cases admitted. Out of 51 cases in which the duration of the mental attack from its commencement was ascertained, recovery took place in less than nine months in 31 cases. The deaths numbered 83, of whom 46 were males and 37 females, giving a percentage of 9·33 on the average number resident. Senile decay was regarded as being the principal cause of death in 28·9 per cent. of the cases, and general paralysis in 31 per cent. In 14 cases tuberculosis was found post mortem. It appears from the tables that the proportion of certifiable insane belonging to West Ham is greater than that of the whole country.

THE NATIONAL INSURANCE BILL.

THE GENERAL MEDICAL COUNCIL AND THE BILL.

IN reply to the representations to the Government by the General Medical Council,[1] which were communicated to the Chancellor of the Exchequer on Nov. 30th, the President, Sir Donald MacAlister, has received the following letter:—

[COPY.]

Treasury Chambers, Whitehall, S.W.,
7th December, 1911.

DEAR SIR DONALD,—I am much indebted to you, and to the General Council of Medical Education and Registration, for your letter of the 30th November, and for the valuable suggestions it contains with regard to certain provisions of the National Insurance Bill. I am glad that the Bill in its present form is in substantial agreement with these suggestions, as you will see from the following summary, in which they are dealt with seriatim.

(1) It is now explicitly provided in Clauses 74, 75, and 76 (now 80, 81, 82), relating to Scotland, Ireland, and Wales respectively, in the Bill as amended in Report, that in each case at least one of the Insurance Commissioners shall, as in England, be a duly qualified medical practitioner.

(2) The provision in the same clauses that the Commissioners for those countries shall have all the like powers and duties as are conferred on the Insurance Commissioners includes the appointment by them of an Advisory Committee in each case.

(3) A substantial increase has now been made in the number of medical practitioners on the Local Health Committees. Under Clause 55 (now 58) as amended, besides the two appointed by the profession itself and the minimum of one appointed by the Commissioners on each such committee, the County Council is now bound to appoint one additional medical practitioner in every case, or two where the committee reaches the number of 60, or three where it reaches 80.

(4) The provisions of Clause 58 (now 61) constituting Local Medical Committees extend to the other countries as well as to England, such modifications as are required, e.g., in the definitions of area, &c., being secured under the clause relating to the application of the Bill to the particular country. It must be remembered, however, that Ireland stands apart from the other countries because medical benefit is not there provided, and therefore the questions dealt with by Local Medical Committees elsewhere do not there arise.

(5) Clause 16 (4) (now 15 (4)) is limited to systems or institutions existing not when the Act comes into operation, but when it is *passed*.

[1] THE LANCET, Dec. 9th, 1911, p. 1640.

Any attempts to take unfair advantage of this section could be frustrated by the power of the Insurance Commissioners and the Local Health Committees to withhold approval.

(6) The relation of the Insurance Bill to hospitals and other voluntary institutions has been very carefully considered; and I am confident that the extreme statements that have been made as to its effect on voluntary subscriptions will not prove to have been justified. If experience should show that the danger is to any extent real and serious the nation may be trusted to see that steps are taken to prevent the efficiency of the hospital system being impaired.

Yours sincerely,
(Signed) D LLOYD GEORGE.

Sir Donald MacAlister, K.C.B., President, General Council of Medical Education and Registration of the United Kingdom.

THE BRITISH CONSTITUTION ASSOCIATION AND THE BILL.

The council and committee of the British Constitution Association petitioned the House of Lords in respect of the Bill, and concluded as follows:—

It is respectfully represented to your Lordships that the National Insurance Bill now under your Lordships' consideration was not even in outline subjected to the judgment of the Electorate at the last, or any, General Election; that so far as it seeks to compel large sections of His Majesty's subjects to contribute to an Insurance Scheme which may, or may not, commend itself to their judgment, it introduces a novel principle into our Legislative system, the effects of which cannot fail to be far-reaching, and may prove highly disastrous; that it has been passed by the House of Commons without adequate opportunity having been afforded for the discussion of many of its most important provisions, and that a Measure so drastic and so exceptional should not be passed into Law until it has been subjected to further examination and discussion within the Houses of Parliament, and in the Country.

Your Petitioners humbly pray that your Honourable House may either reject the Bill,

OR

In the event of the Bill being passed (whether amended or not by your Lordships) that a Clause may be added providing that the Measure shall not become law until it has been submitted to the judgment of the Electors at a Special Poll to be taken for the purpose in such a manner as Parliament may provide.

And your Petitioners as in duty bound will ever pray, &c.

The House of Lords has had the same view forcibly put before it, no doubt, by many people, but it has been generally foreseen that the peers will pass the Bill practically without comment.

As we go to press a meeting of the British Constitution Association is being held, under the presidency of Lord Robert Cecil, M.P., to protest against the National Insurance Bill becoming law "before the country has had full time to consider the measure."

THE BRITISH MEDICAL ASSOCIATION AND THE BILL.

The following circular from the medical department of the British Medical Association, dated Dec. 11th, gives the opinions of the chairman of Representative meetings and the chairman of the Council as to how much has been obtained for the medical profession under the Insurance Bill and what still remains to be obtained:—

1. On June 1st, 1911, the British Medical Association adopted the following policy with respect to the Insurance Bill, and circularised every member of the profession asking for support of the following six essential principles: (1) An income limit of £2 a week for those entitled to medical benefit; (2) free choice of doctor by patient subject to consent of doctor to act; (3) medical and maternity benefits to be administered by Local Health Committees and not by Friendly Societies; (4) the method of remuneration of medical practitioners adopted by each Local Health Committee to be according to the preference of the majority of the medical profession of the district of that committee; (5) medical remuneration to be what the profession consider adequate, having due regard to the duties to be performed and other conditions of service; (6) adequate medical representation among the Insurance Commissioners, in the Central Advisory Committee, and in the Local Health Committees, and statutory recognition of a Local Medical Committee, representative of the profession in the district of each Health Committee.

2. On June 15th the members of the profession were asked to pledge themselves, in the event of the Bill becoming law, not to enter into arrangements for the treatment of insured persons on terms inconsistent with the above declared policy of the Association.

3. The Insurance Bill will probably become law within the next fortnight, and the Association and profession have to consider their future action towards it.

4. The policy of the Association as expressed in the above stated six cardinal principles is absolutely unchanged.

5. The Bill by the efforts of the Association has now been so amended that there is no legal barrier against the profession securing the fulfilment of its entire policy.

6. The following principles of the Association have been incorporated in the Bill as it has now left the House of Commons, viz., the free choice of doctor, the administration of medical and sanatorium benefits by the Local Health Committee, the representation of the profession on all the administrative bodies established under the Act; the statutory recognition of a committee of the medical profession in each district.

In addition the essential principle of a wage limit is recognised by Clause 15 (3) in the Bill, the precise amount being fixed by the profession in each district in negotiation with the Local Health Committee.

7. The remaining principles of the policy of the Association not dealt with under the Bill are the rate and method of remuneration and the amount of the wage limit. The first of these, the most essential of the principles of the Association, the Representative Body decided should be settled by agreement between members of the profession in each district and the Local Health Committee. As regards the second, it decided that this also if not embodied in the Bill should be fixed by local negotiation.

8. The Association, through the Representative Body, has taken every possible step to secure that in every locality where its assistance is required, the whole resources and strength of the Association shall be used to support the profession in securing the essential principles.

9. If each member of the profession will do his share in this great work he may fully rely upon the organisation of the Association being both ready and adequate to secure success.

(Signed) EWEN J. MACLEAN,
Chairman of Representative Meetings.
J. A. MACDONALD,
Chairman of Council.

Medical Department, British Medical Association, London, Dec. 11th, 1911.

MEETINGS OF THE MEDICAL PROFESSION.

As we go to press a mass meeting of the medical profession is being held at the Midland Hall, Midland Hotel, Manchester. Mr. G. A. Wright has been announced to take the chair. Medical men from all parts of the country have been invited. Resolutions will be proposed "calling upon all medical men to take no office under the Bill," and to form a temporary union to deal with the situation.

A meeting has been convened by an influential group of medical men for Tuesday next, Dec. 19th, at 4.30 P.M., at the Queen's Hall, Langham-place. A preliminary meeting has been held to draft the resolutions and showed that the general tone of these will be strong, their sense being to imply that existing associations have failed to safeguard the interests of the profession, and that a further union of medical men is required. Sir W. Watson Cheyne will preside over the meeting.

A representative meeting of medical practitioners in the Ilford district was held on Dec. 5th, in the Recorder Buildings, with the object of securing unity of action and of determining the main principles which should guide the profession in its work with the National Insurance Scheme in this locality. After some discussion a resolution was moved and carried unanimously to the effect that the meeting forms itself into the "Ilford Medical Union," to secure joint action locally, and through the British Medical Association nationally, with the rest of the profession, to safeguard the interests of the profession and the health of the public; to endeavour to secure fair rates of remuneration and fair conditions of employment under the National Insurance Scheme. All the medical men practising in the district who were prevented from attending the meeting have signified their agreement with the resolution, and their intention to join the union.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns, having an estimated population of 16,157.797 persons in the middle of this year, 7506 births and 4718 deaths were registered during the week ending Dec. 9th. The annual rate of mortality in these towns, which had steadily increased from 13·1 to 15·7 in the four preceding weeks, declined to 15·2 per 1000 in the week under notice. During the first ten weeks of the current quarter the mean annual rate of mortality in these towns averaged 14·3 per 1000, and was 0·4 per 1000 above that recorded in London during the same period. The annual death-rates in the 77 towns last week ranged from 6·8 in Hornsey, 7·1 in Willesden and in Walthamstow, 7·8 in East Ham, and 8·6 in Bournemouth to 21·5 in Walsall, 21·7 in Sunderland, 22·2 in Preston, and 23·0 in Stockton-on-Tees. The 4718 deaths from all causes in the 77 towns were 151 fewer than the number in the previous week, and included 238 which were referred to the principal epidemic diseases, against 259 and 276 in the two preceding weeks. Of these 238 deaths, which was the lowest aggregate number recorded in any week of the current year, 60 resulted from diphtheria, 52 from measles, 45 from whooping-cough, 45 from infantile

diarrhœa, 20 from enteric fever, and 16 from scarlet fever, but not one from small-pox. The mean annual death-rate from these epidemic diseases last week was equal to 0·8 per 1000, against 0·8 and 0·9 per 1000 in the two previous weeks. The deaths attributed to diphtheria, which had been 64, 61, and 57 in the three preceding weeks, rose to 60 last week, and included 16 in London and its suburban districts, 4 in Bradford, 3 in Leicester, and 3 in Liverpool. The deaths referred to measles, which had been 51, 44, and 66 in the three preceding weeks, declined last week to 52, and of these 9 occurred in London, 8 in Norwich, 7 in Liverpool, 5 in Burnley, 4 in Nottingham, and 3 in Salford. The fatal cases of whooping-cough, which had steadily risen from 16 to 38 in the five preceding weeks, further rose to 45 last week; 11 deaths were registered in London and its suburban districts, 6 in Walsall, and 3 each in Birmingham, Sheffield, and Newcastle-on-Tyne. The deaths of infants under two years of age attributed to diarrhœal diseases, which had continuously declined from from 2714 to 68 in the 15 preceding weeks, further fell to 45 last week, and included 11 in London, 4 in Birmingham, 4 in Manchester, and 3 in Grimsby. The 20 deaths referred to enteric fever last week were 3 below the average number in the four preceding weeks, and included 2 each in London, Liverpool, Burnley, and Sheffield. The fatal cases of scarlet fever, which had been 29 and 25 in the two preceding weeks, further declined to 16 last week; 3 deaths were recorded in London, 2 in Liverpool, and 2 in Manchester. The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had been 2213, 2166, and 2141 at the end of the three preceding weeks, had further declined to 2089 at the end of the week under notice; 241 new cases of this disease were admitted to these hospitals during the week, against 291, 203, and 248 in the three preceding weeks. These hospitals also contained on Saturday last 1306 cases of diphtheria, 194 of whooping-cough, 83 of measles, and 79 of enteric fever, but not one of small-pox. The 1239 deaths from all causes in London last week were 67 fewer than the number in the previous week, and included 331 which were referred to diseases of the respiratory system, against numbers steadily rising from 170 to 297 in the five preceding weeks. The deaths attributed to different forms of violence in the 77 towns, which had been 158 and 188 in the two preceding weeks, further rose to 201 last week, and 420 inquest cases were registered. The causes of 44, or 0·9 per cent., of the deaths registered in the 77 towns last week were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in London and its eight suburban districts, Bristol, Bradford, Newcastle-on-Tyne, Nottingham, Salford, and in 42 other smaller towns. The 44 uncertified causes of death last week included 9 in Birmingham, 7 in Liverpool, 5 in South Shields, and 3 in Gateshead.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns, having an estimated population of 1,710,291 persons in the middle of this year, 796 births and 550 deaths were registered during the week ending Dec. 9th. The annual rate of mortality in these towns, which had been 16·7 and 18·0 in the two previous weeks, declined to 16·8 per 1000 in the week under notice. During the first ten weeks of the current quarter the mean annual death-rate in these Scotch towns averaged 16·7, and was 2·4 per 1000 above the mean rate during the same period in the 77 large English towns. The annual death-rates in the several Scotch towns last week ranged from 14·1 and 14·5 in Edinburgh and Perth to 18·5 in Aberdeen and 24·3 in Greenock. The 550 deaths from all causes were 39 fewer than the number in the previous week, and included 58 which were referred to the principal epidemic diseases, against 63 and 72 in the two preceding weeks; of these 58 deaths, 23 resulted from measles, 10 from whooping-cough, 9 from diarrhœal diseases, 8 from diphtheria, 5 from enteric fever, and 3 from scarlet fever, but not one from small-pox. The mean annual death-rate from these epidemic diseases in the eight towns last week was equal to 1·8, and was 1·0 per 1000 above the mean rate from the same diseases in the 77 large English towns. The deaths referred to measles, which had been 28, 23, and 31 in the three preceding weeks, declined to 23 last week, and included 13 in Aberdeen, 7 in Glasgow, and 2 in Greenock. The deaths attributed to whooping-cough, which had been 4, 7, and 6 in the three preceding weeks, rose last week to 10, of which 5 were registered in Aberdeen and 3 in Glasgow. The deaths assigned to diarrhœal diseases, which had been 16 in each of the two previous weeks, declined last week to 9, all but one of which related to infants under two years of age; 3 deaths were recorded in Glasgow, 3 in Paisley, and 2 in Dundee. The fatal cases of diphtheria, which had been 7 and 15 in the two preceding weeks, declined to 8 last week, and of these 2 occurred in Glasgow and 2 in Leith. The 5 deaths attributed to enteric fever were 3 in excess of the average in the three preceding weeks and were all recorded in Glasgow. The 3 fatal cases of scarlet fever were registered in Glasgow, Paisley, and Greenock respectively. The deaths referred to diseases of the respiratory system, which had been 113 in each of the two preceding weeks, increased to 122 last week, but were 29 below the number recorded in the correspondir g week of last year. Of the deaths from all causes in the Scotch towns last week, 144, or 26 per cent., were recorded in public institutions, and 19 were attributed to different forms of violence. The causes of 16, or 2·9 per cent., of the deaths in the eight towns in the week under notice were not certified or not specified; in the 77 large English towns the proportion of uncertified causes last week did not exceed 0·9 per cent.

HEALTH OF IRISH TOWNS.

In the 22 town districts of Ireland, having an estimated population of 1,149,495 persons in the middle of this year, 502 births and 391 deaths were registered during the week ending Dec. 9th. The annual rate of mortality in these towns, which had been 18·0 and 18·3 in the two previous weeks, declined to 17·7 per 1000 in the week under notice. During the first ten weeks of the current quarter the mean annual death-rate in these Irish towns averaged 18·2 per 1000; in the 77 large English towns the mean annual death-rate during the same period did not exceed 14·3, while in the eight Scotch towns it was equal to 16·7 per 1000. The annual death-rate last week was equal to 18·6 in Dublin (against 14·3 in London), 16·1 in Belfast, 26·5 in Cork, 19·2 in Londonderry, 16·3 in Limerick, and 20·9 in Waterford; while in the 16 smallest of these Irish towns the death-rate last week did not exceed 15·1 per 1000. The 391 deaths from all causes were 12 fewer than the number in the previous week, and included 25 which were referred to the principal epidemic diseases, against numbers declining from 47 to 40 in the three preceding weeks; of these 25 deaths, 7 resulted from diarrhœal diseases, 6 from whooping-cough, 4 from scarlet fever, 4 from diphtheria, 2 from measles, 1 from enteric fever, and 1 from typhus, but not one from small-pox. These 25 deaths from the principal epidemic diseases were equal to an annual death-rate of 1·1 per 1000; in the 77 English towns the mean annual death-rate from these diseases last week did not exceed 0·8 per 1000, while in the eight Scotch towns it was equal to 1·8. The deaths attributed to diarrhœal diseases, which had been 19, 19, and 14 in the three preceding weeks, further declined last week to 7, all of which related to infants under 2 years of age; 4 deaths were recorded in Dublin and 2 in Belfast. The deaths referred to whooping-cough, which had been 11 in each of the two preceding weeks, declined to 6 last week, and comprised 3 in Dublin, 2 in Belfast, and 1 in Lurgan. The 4 fatal cases of scarlet fever were equal to the average in the five preceding weeks. The 4 deaths assigned to diphtheria, of which 2 were recorded in Belfast, were equal to the average in the two preceding weeks. The deaths referred to measles numbered 2, against 4 in each of the two preceding weeks, and were registered in Dublin and Cork respectively. The fatal case of enteric fever was recorded in Dublin, and that of typhus in Cork. The deaths referred to diseases of the respiratory system, which had been 73, 78, and 77 in the three preceding weeks, rose to 92 last week. Of the 391 deaths from all causes in the Irish towns last week, 125, or 32 per cent., were recorded in public institutions, and 9 were attributed to different forms of violence. The causes of 13, or 3·3 per cent., of the deaths in the 22 towns last week were not certified either by a registered medical practitioner or by a

coroner after inquest; the proportion of uncertified causes in the week under notice did not exceed 0·9 per cent. in the 77 English towns, but was equal to 2·9 per cent. in the eight Scotch towns.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

Fleet-Surgeon Patrick Brodie Handyside has been promoted to the rank of Deputy Surgeon-General in His Majesty's Fleet (dated Nov. 25th, 1911).

ROYAL ARMY MEDICAL CORPS.

Colonel F. H. Treherne has taken up duty at Bangalore as Principal Medical Officer of the Bangalore and Southern Brigades. H.E. the Viceroy and Governor-General of India has been pleased to appoint Brevet-Colonel R. H. Firth, sanitary officer, army headquarters, Simla, to his personal staff as Honorary Surgeon in succession to Colonel R. H. Forman, retired. Lieutenant-Colonel W. C. Beevor, C.M.G., lately commanding the Station Hospital at Bangalore, has taken over charge of the Military Hospital at Fermoy. Lieutenant-Colonel R. L. R. Macleod, lately commanding the Station Hospital at Aden, has been selected for the higher rate of pay under Article 317 of the Royal Warrant. Lieutenant-Colonel R. W. Wright has been appointed to command the Station Hospital at Fyzabad for a period of three years. Lieutenant-Colonel J. Fallon, from Preston, has embarked for a tour of service with the Northern Army in India, and on arrival will be posted to the Third (Lahore) Division. Lieutenant-Colonel C. E. Nichol, at present commanding the Station Hospital at Maymyo, Burma, has been granted an extension of his Indian tour of service until further orders. Lieutenant-Colonel B. J. Inniss has been transferred from the Eastern Command to the Irish Command. Major J. D. Mc D. McCarthy has taken up duty as Specialist Sanitary Officer to the Second (Rawal Pindi) Division, in succession to Major F. Smith, D.S.O., transferred to command the Station Hospital at Calcutta. Major M. P. Corkery, in medical charge of the Lawrence School and Residency Surgeon at Mount Abu, has arrived home on six months' leave of absence. The leave granted to Major R. J. Copeland, from Meerut, has been extended by six months on the recommendation of a medical board. Major H. O. B. Brown-Mason has been appointed Specialist in Dermatology and Venereal Diseases to the Sixth (Poona) Division. Major E. M. Morphew, on transfer to the Home Establishment from India, has been posted for duty to the Western Command. Major J. A. Hartigan has taken up duty in North China. Major J. G. Gill has been transferred from Secunderabad to the Station Hospital at Bangalore. Major W. H. S. Nickerson, V.C., from Rawal Pindi, has joined for duty at Cherat. Major B. Watts has been appointed Specialist in Midwifery and Diseases of Women and Children to the Seventh (Meerut) Division. Major A. F. Carlyon, from Devonport, has embarked for a tour of duty at Mauritius by exchange with Captain M. Foulds, surgical specialist at Belfast. Major G. W. Tate has taken up duty in Ireland as Medical Inspector of Recruits. Captain F. M. Parry, from Maidstone, has embarked for a tour of duty at Mauritius. Captain S. E. Lewis has taken up charge of the Military Families Hospital at Devonport. Captain R. G. Archibald has arrived home on leave of absence from Egypt. Captain C. D. Myles has been transferred from the Southern Command to the Western Command. Captain F. P. Lauder, from Cork, has been appointed to Youghal for duty. Captain A. D. Jameson, specialist in dermatology and venereal diseases to the Aldershot Command, has embarked for a tour of service with the Northern Army in India. Captain D. L. Harding, from Athlone, has taken up duty at Belfast. Captain C. E. Fleming, from Colchester, has arrived for a tour of duty in South Africa. Captain C. R. Sylvester-Bradley, from Cosham, has been appointed Adjutant to the Royal Army Medical Corps School of Instruction, Eighth (Wessex) Division, at Exeter, in succession to Major R. H. Lloyd, whose tenure of the appointment has expired. Captain A. H. McN. Mitchell, specialist in ophthalmology at the Royal Victoria Hospital, Netley, has been placed under orders by the War Office for a tour of service in Jamaica. Captain J. E. Powell has been transferred from the Northern Command to Alderney. Captain F. J. Stuart, from Fyzabad, has taken up duty at Meerut Cantonment. Captain C. A. T. Conyngham, from the Station Hospital at Quetta, has been detailed for a course of instruction in X-Ray Management at the Dehra Dun X-Ray Institute. Lieutenant E. C. Stoney, at present in charge of the Military Families Hospital at Colchester, has been detailed by the War Office for a tour of service in India during the present trooping season. Lieutenant R. H. Nolan, serving at Barian Military Hospital, Murree Hills, has been granted eight months' leave of absence home, on the recommendation of a medical board. Lieutenant A. D. Stirling, from Piershill, has taken up duty at Alexandria. Lieutenant T. J. Hallinan has been transferred from Youghal to the Military Hospital at Limerick.

INDIAN MEDICAL SERVICE.

Surgeon-General W. S. Bannerman, Surgeon-General with the Government of Madras, has been appointed to the suite of His Excellency the Governor of Madras during the Coronation Durbar at Delhi. Colonel D. ffrench-Mullen, deputy principal medical officer of His Majesty's Forces in India, has been selected for appointment as Principal Medical Officer of the Sirhind and Jullundur Brigades, in succession to Colonel H. Hendley. The Honourable Lieutenant-Colonel S. H. Henderson, Inspector-General of Prisons in the United Provinces of Oudh and Rohilkhand and Member of the Administrative Council, has been appointed to the suite of His Excellency the Lieutenant-Governor of the United Provinces during the Coronation Durbar at Delhi. Lieutenant-Colonel E. Jennings, superintendent of the Central Prison at Farrukhabad, United Provinces, has been granted privilege leave of absence, combined with furlough, for a total period of two years. Major C. B. Harrison has arrived home on leave of absence from Madras Presidency. The services of Major W. H. Roberts, plague medical officer in the Punjab, have been placed at the disposal of the Home Department of the Government of India. On return from furlough Captain G. G. Swan has been appointed to Ludhiana as Civil Surgeon, in succession to Captain M. Corry, who has been appointed Civil Surgeon at Mooltan. Captain H. C. Keates, at present officiating as civil surgeon at Jullundur, has been directed to proceed to Dehra Ghazi Khan as Civil Surgeon on relief by Major J. Peck, returning from furlough. Captain J. W. H. Babington has arrived home on leave of absence from India. Captain E. C. Hepper has been appointed to the medical and sanitary charge of the United Provinces Camps at the Coronation Durbar at Delhi. Captain E. T. Harris has been granted four months' extension of his leave of absence home by the Right Honourable the Secretary of State for India. Captain M. C. Kendrick has been appointed to officiate as Statistical Officer to the Government of India in the Medical and Sanitary Departments during the leave of absence of Major S. P. James. Captain C. Gill has taken up duty as Officiating Civil Surgeon at Simla during the absence on leave of Lieutenant-Colonel C. Duer. Captain N. S. Wells has received one month's extension of his leave of absence on the recommendation of a medical board. Captain F. O. D. Fawcett and Captain G. M. Millar have returned to India on the expiration of their leave. Captain Armytage Green, on appointment to the Civil Medical Department, has been posted to Jalpaiguri as Civil Surgeon. Captain E. A. Walker, civil surgeon at Bassein, has been granted leave of absence, combined with furlough, for a total period of two years. The services of Captain A. N. Dickson have been placed temporarily at the disposal of the Government of the United Provinces for plague prevention duty. His Excellency the Governor of Bombay in Council has been pleased to appoint Captain C. C. Murison to officiate as Superintendent of the Medical School at Hyderabad during the absence on deputation of Lieutenant-Colonel B. B. Grayfoot. Captain J. L. Lunham has been selected for appointment as Personal Assistant to the Surgeon-General with the Government of Bombay, in succession to Captain R. M. Barron, whose services have been replaced at the disposal of the Government of India.

TERRITORIAL FORCE.

Royal Army Medical Corps.

3rd Highland Field Ambulance, Royal Army Medical Corps: Lieutenant Arthur M. Davie to be Captain (dated Nov. 2nd, 1911).

1st East Lancashire Field Ambulance, Royal Army Medical

Corps: Major William Leonard Bentley, from the 3rd East Lancashire Field Ambulance, Royal Army Medical Corps, to be Major, with precedence in the unit as from April 1st, 1908, next above Major Herbert G. Parker (dated May 20th, 1911)

2nd East Lancashire Field Ambulance, Royal Army Medical Corps: Major William Bridgett Pritchard, from the 1st East Lancashire Field Ambulance, Royal Army Medical Corps, to be Major, with precedence in the unit as from April 1st, 1908, next above Major Fred D. Woolley (dated May 20th, 1911).

3rd South Midland Field Ambulance, Royal Army Medical Corps: Lieutenant George Scott Williamson, from the Yorkshire Mounted Brigade Field Ambulance, Royal Army Medical Corps, to be Lieutenant (dated Oct. 5th, 1911)

2nd Wessex Field Ambulance, Royal Army Medical Corps: Lieutenant Robert Burnet to be Captain (dated Oct. 1st, 1911).

THE DURBAR HONOURS.

In connexion with the crowning of His Majesty the King as Emperor of India a long list of honours has been issued rendering necessary a statutory increase in the numbers of the two Indian Orders. Among the members of the medical profession in the list is the name of Surgeon-General Charles Pardey Lukis, C.S.I., the Director-General of the Indian Medical Service and an additional member of the Council of the Governor-General of India for making Laws and Regulations, who has been promoted to a Knight Commandership of the Order of the Star of India. Surgeon-General Francis Wollaston Trevor, C.B., K.H.S., Principal Medical Officer in India, has also received a similar honour.

Among the Companions of the Order of the Star of India are the names of Lieutenant-Colonel William Burney Bannerman, I.M.S., Surgeon-General with the Government of Madras, and lately Director of the Bombay Bacteriological Laboratory; Colonel George Francis Angelo Harris, V.H.S., Inspector-General of Civil Hospitals, Bengal; and Lieutenant-Colonel Arthur Russell Aldridge, R.A.M.C., lately Sanitary Officer at the Army Headquarters.

In the list of Knights Commanders of the Order of the Indian Empire is the name of Surgeon-General Arthur Mudge Branfoot, C.I.E., I.M.S. (retired), President of the Medical Board of the India Office. Among the Companions of the Order are the names of Lieutenant-Colonel Charles MacTaggart, I.M.S., Inspector-General of Prisons, United Provinces of Agra and Oudh; Major Leonard Rogers, I.M.S., professor of pathology at the Medical College, Calcutta, and bacteriologist to the Government of India; Major Henry Burden, I.M.S., residency surgeon in Nepal; Lieutenant-Colonel James Reed Roberts, I.M.S., residency surgeon in Indore and administrative medical officer in Central India; and Major Frederick Fenn Elwes, I.M.S., surgeon to the Governor of Madras.

The Royal Victorian Order includes the name of Colonel Charles James Bamber, I.M.S., Inspector-General of Civil Hospitals, Punjab, and a member of the Coronation Durbar committee, who receives the C.V.O.

Lieutenant-Colonel Charles Henry Bedford, I.M.S., chemical examiner, Bengal, has been made a Knight Bachelor.

The following officers have received the "Kaisar-i Hind Medal for Public Service in India" of the First Class:—Major Albert Elijah Walter, I.M.S., superintendent of the X-Ray Institute, Dehra Dun; Major Arthur Gwyther, I.M.S., civil surgeon, Howrah, and superintendent of the Howrah Jail; Surgeon Lieutenant-Colonel Thomas Joseph O'Donnell, K.G.F. Vols., V.D., lately chief medical officer Kolar Gold Fields; Captain Jasper Robert Joly Tyrrell, I.M.S., agency surgeon at Bhopawar, Central India; and Major William Hancock Tucker, I.M.S., district medical and sanitary officer, Coimbatore, Madras Presidency.

We offer, in the name of the medical profession, our hearty congratulations to all these gentlemen.

BRIDGWATER HOSPITAL.—The annual meeting of subscribers to this hospital was held recently. The financial statement showed that there was an unfavourable balance of £1132 against the charity. It was stated that a carnival will be held next summer in order to raise funds for the hospital. It was decided to raise a fund for building a new wing, as additional accommodation was much needed.

Correspondence.

"Audi alteram partem."

THE NATIONAL INSURANCE BILL.

To the Editor of THE LANCET.

SIR,—May I beg the hospitality of your columns to publish as widely as possible the fact that it has been decided to hold a meeting of the medical profession at 4 o'clock on Tuesday afternoon, Dec. 19th, in the Queen's Hall, Langham-place. Sir W. Watson Cheyne has kindly consented to take the chair.

I would like to explain that this meeting will not concern itself in any formal manner with the recent action of the Council of the British Medical Association: it obviously arises out of that action, but as no possible good could come from discussing that point in public any further it will be entirely omitted from the meeting which is intended to be one open to the whole profession.

The objects of the meeting will be confined to: 1. Protesting against the Bill in its present form by a resolution probably on the lines of those which are now being proposed in various centres. 2. Strengthening the hands of all associations of medical men which are assisting in the same object.

It is earnestly hoped that as many medical men as possible throughout the Kingdom will do their very best to attend, as the present situation of the profession under the Bill as it stands seems to be very critical.

I am, Sir, yours faithfully,

Harley-street, W., Dec. 11th, 1911. FRED. J. SMITH.

To the Editor of THE LANCET.

SIR,—The Insurance Bill will undoubtedly in a few days become the Insurance Act. The British Medical Association undertook to negotiate with the Government for the medical profession. The time has now come when we are bound to ask what has been the outcome of these negotiations. Like other members of the British Medical Association, I have received a memorandum signed by the chairman of the Representative Meetings, and the chairman of the Council, dated Dec. 11th. It seems to express some satisfaction with the result of the action of the Council, but I think this satisfaction will be found to be enjoyed by the members of the Council only. It is needless to discuss the "six essential principles" of which we have heard so much. The great outstanding fact is that while the Bill declares exactly what the insured are to contribute and what sickness benefit they are to receive, the members of the medical profession who are called upon to afford "free medical attendance" are not informed how or how much they are to be paid for their services. Whatever value may attach to the "six essential principles" so dear to the Council of the British Medical Association, the great fact that looms large in the estimation of every practitioner in the country is that while the Bill demands from him an unknown amount of professional service, it makes no definite provision for his adequate payment. It is to the clearing up of this doubt and uncertainty that we should now devote all our attention, and whatever may be thought of the action of the Council in regard to other matters I myself feel that their great default has been in dissipating their strength upon minor matters, and leaving untouched and to be fought out with every Local Insurance Committee by smaller bodies of practitioners, seriously handicapped in the encounter, the one essential issue. Even yet much may be done if only the profession will hold together and are wisely led.

I am, Sir, yours faithfully,

ALFRED PEARCE GOULD.

Queen Anne-street, Cavendish-square, W., Dec. 13th, 1911.

To the Editor of THE LANCET.

SIR,—The intense feeling which has in the last few days been stirred up against the Council of the British Medical Association appears to me to arise mainly from a want of knowledge of the real state of affairs. This feeling, if allowed to grow, will inevitably destroy the unity of the profession which has been so recently and so hardly achieved,

and this will render us powerless in the face of our opponents.

The facts of the case.—My own view as to the true state of affairs is as follows. The governing body of the Association is the representative meeting, an elected body which voices the feelings of the members in all the divisions and which declares the policy of the Association. The Council is the executive body which works out the details of the policy laid down by, and carries out the instructions of, the representative meeting. The policy of the Association, as declared by the representative meeting, has been arrived at only after careful consideration and after consulting the individual members in the divisions. Of course, with such an exceedingly complicated measure as the Insurance Bill it was impossible that there should be absolute unanimity in the views taken by the many thousands of members of the Association. In some cases the minority had to give way to the majority; in others divergent opinions were reconciled by taking an intermediate course. Thus the policy adopted was in the nature of a compromise amongst ourselves. But the net result was that in the end we did arrive at a policy on which we could all unite and which we could use as a common base from which to fight.

The policy adopted.—We agreed that we would not oppose the Bill at the outset, but that we should endeavour to have it amended and improved. We agreed on six cardinal principles which were to serve as the bedrock of our demands. We agreed that as many as possible of the points in these cardinal principles should be incorporated in the Bill, and that those which were not so incorporated we should insist on having provided in the regulations to be drawn up by the Commissioners. We agreed that if these six cardinal principles were not granted we would oppose, with all our power, the acceptance by medical men of the duties of providing medical attendance to the insured. With this end in view the majority of practitioners in the country signed a "pledge" to refuse to undertake the medical attendance of the insured under the Bill unless the six cardinal principles had been conceded.

An axiom.—In a voluntary association like ours, if we are to achieve any success by united action against powerful antagonists, we must take it as an axiom that where a minority has been constitutionally outvoted it must be willing to sink its minority views and to agree to act loyally with the majority in asserting the views that have been agreed upon for the general good.

Points of cleavage.—All through this adopted policy there appear what I may call points of cleavage when a number of members, sometimes from one section, sometimes from another, wished to take a line differing from that favoured by the majority. And when this has occurred, unless the minority is willing to fall in with the axiom I have just given, the Association will have its unity destroyed and as a power for enforcing the views of the whole body of members it will be reduced to impotence.

Let us look at some of these points of cleavage. First, there were a number of members who wished to have nothing to do with the Bill, and who were unwilling that we should take any part in endeavouring to improve the provisions of the Bill. These views have been negatived in the three successive representative meetings held this year. Then there were many who wished to have all the six cardinal principles embodied in the Bill itself. But this was recognised to be an impossibility. The policy, therefore, adopted by the representative meeting was that those points, which we could not get inserted in the Bill, were to be obtained in the regulations still to be framed by the Commissioners. Then, again, the "pledge" agreed to only referred to the medical treatment of those insured. Some men wanted a similar "pledge" to cover administrative posts under the Bill, such as Commissionerships. But when a resolution to this effect was proposed at the last representative meeting it was recognised that the passing of it would defeat our own objects, as unless we had satisfactory representation amongst the Commissioners we could not hope to have the regulations drafted to our satisfaction. This proposal was therefore, *with the consent of the meeting*, withdrawn.

What the Council have done.—From what I have said I think it is clear that the Council have so far faithfully carried out the instructions of, and the policy laid down by, the representative meeting. On the particular question which has raised all this dangerous storm—the appointment of Mr. Smith Whitaker—I would like to accentuate the fact that medical representation amongst the Commissioners is one of the points in the six cardinal principles for the granting of which we have been clamouring for the last seven months, and the withdrawal of the motion to apply the "pledge" to executive posts clearly implied, to me at least, that the representative meeting did not wish to hamper the Council in getting the best possible medical man appointed as a Commissioner. I have not yet heard it seriously suggested that we could get any better man for our purpose than Mr. Smith Whitaker. The idea of our Association being split into factions on the question of the precise method of the acceptance of this post would be absurd if it were not so serious.

The responsibility of the members.—If all those who have differed from the majority at any of the various points of cleavage are now to be added together as opponents of the policy of the Association, as adopted by the representative meeting, then, of course, we may find that they make a majority against this policy. But this method of working is absolutely contrary to the axiom I have propounded as essential to any satisfactory unity in the work of a voluntary association. That way lie anarchy and destruction. If the policy adopted by the Association be wrong, that is the fault of the members themselves or of their representatives. Certainly it is not the fault of the Council. I have heard it stated that the representative meeting is led by the nose by a few pushing members of the Council. This, of course, is absurd; but, even if it were true, it would still be the fault of the members for sending up such weaklings as representatives.

Danger of dissension.—Will not those who are forcing this split upon us realise, before it is too late, that they are simply playing the game of our opponents? It is idle to talk of the hasty formation of a new union at this stage in the fight. Even if it could be got ready as a fighting machine in time to be of any service, let us remember the old proverb about the danger of swapping horses when crossing the water. To attempt any new formation now is fatal, it simply means disunion and destruction. Our only strength is in unity. Our one weapon—first, last, and all the time—is refusal to undertake the treatment of the insured when the time comes. That weapon is as strong now as ever if we can only retain our unity. Those responsible for the Bill have been warned that we have this weapon ready, and that we shall not hesitate to use it. We are all of us justly indignant at the way we have been treated and our interests ignored by those who drafted the Bill. We are certainly united on the main issue, that we will not work the Bill unless the conditions offered are satisfactory to us. We can win, if we will only stand together. Why, then, because we are sore and irritated at the treatment we have received from others, should we lose our heads, quarrel amongst ourselves, and thus destroy our chances of success by a bitter disruption over questions which are, after all, only those of tactics and procedure?

I am, Sir, yours faithfully,

Harrow, Dec. 12th, 1911. ALFRED H. WILLIAMS.

To the Editor of THE LANCET.

SIR,—One can but regret that the admirable logic and wit of Dr. B. Hall is being wasted on a deservedly lost cause. If we pursue his argument to its conclusion, our practices would be so magically transformed by *per capita* payments that when we were busiest we should be saddest, and we should only be happy when we had no work to do. Would this state of mind really conduce to our patient's welfare, let alone our own? Much as we should all love to join with him in our client's tears and laughter, may I remind him that a good physician's duty to smile occurs precisely when the patient is weeping; and we are fortified in this difficult task by the knowledge that we are paid per attendance—i.e., per chortle. Dr. Hall's seems to be an individual and temperamental view; whereas the ordinary method of payment per attendance is based on the permanent springs of human nature, and rests on that fundamental community of interest underlying all fruitful labour—namely, the exchange of good individual work for good individual payment. Any transaction in which the payment is a known fixed sum and the work an unknown variable quantity stamps itself as a gamble. I recognise in

Dr. Hall a true sportsman, but I must persist in declining to join him in turning my actual occupation into a gamble against time and chance, with the dice loaded on the side of the State. Even without *per capita* payments a little philosophy will enable me to smile when the surgery is empty; and a little sympathy will enable me to present a cheery face when it is full, thus bettering Dr. Hall's attitude by dispensing altogether with the tears.

Dr. Hall and Mr. Penrose Williams must not suppose that their arguments are unanswerable nor that "silence gives consent." The arguments against *per capita* and for per attendance payments have appeared in abundance in our journals for months past; I would only add one out of many, if you have room for it, of a more general nature. Mr. Williams considers that "the one objection to the practice of medicine is the daily valuation of one's services." The art of medicine is, and always will remain, a mystery to the public, who do not know what we put into our bottles, and, if they did, would be equally ignorant of both of its commercial and therapeutic value. The public, therefore, have only two means of estimating the value of our services: (1) the apparent care we take of them, measured by our visits and their results; (2) the money they pay us per visit. Hence in their eyes their money is measured and balanced by our visits, which form a manifest measure of the value received by them.

What, in our consciences, is our aspect of the matter? We know that our medicines alone are commercially the smallest item, and therapeutically but a small item, in the things we give them; but our *visits* include our advice and care, and we add them to the credit balance as the major item in the ledgers of our conscience. In fact, our sense of honour compels us to earn the money of each visit by giving to each visit the utmost of our care. It is precisely the daily money valuation of our visits, to which Mr. Williams objects, which induces us to give value for money, because this value cannot, as in ordinary exchange and barter, be *exacted* from us by the buyer (*caveat emptor*), on account of his ignorance of the true items in what he is receiving. On the two standards by which he judges, what value will he place on services obtained for 4*s.* a year? He will value them just at four shillings' worth; and, what is more, he will eventually get just that value and no more, for in the long run services of unlimited scope so paid for will be corrupted and restricted so as to be of that value and no more. Can this be good doctoring?

The clients of most of us, from reasons of expense, only call us in when they need. Our existing practices are founded on this basis. "Free doctoring" at an annual fixed payment will reveal a tenfold number of calls, clients who had previously called me in only in emergencies, and according as they could pay, but who will now call me in in innumerable slight illnesses. (Mark that it is all one to me whether the illness is slight or severe; the time and care per attendance which I give them is substantially the same in all cases.) Hence my work will be enormously increased, and three consequences will inevitably attend the system. (*a*) Simple arithmetic on the census proves to me that I can at best, on a *per capita* basis, receive a less income than I now earn. (*b*) While to earn it I am bound to sacrifice all my leisure and health in impossibly enhanced work. Why should any of us accept, still less welcome, this *certain* prospect. It may be pure selfishness, but I prefer the present system of payment for work done, which applies to all other exchanges, and which leaves to both parties to the exchange the responsibility of freely exchanging the service for the payment from day to day. (*c*) This enormously enhanced work can only be coped with by an enormously enhanced number of doctors. Where are they? They do not exist; hence I must do the work of ten. The Chancellor began by admitting that "the doctors are an overworked profession"; can he be surprised that we decline to add to that existing heavy burden an enormously enhanced *new* burden of work?

This view of the problem is entirely apart from the sordid £ *s. d.* aspect, which even the *per capita* advocates, in their altruistic heights, cannot and do not ignore. Mr. Williams himself claims that "the whole thing for us turns on one point only, £ *s. d.*" When one considers the quality of work turned out by overworked people I think it will be admitted that we advocates of "payment per attendance" take a wider and more truly ethical view of the problem than our opponents. Pardon me for attempting to bring out clearly these two of the very many aspects of the problem; practical aspects which none of the opposing letters, admirable as they are in logic and theory, have even touched.

I am, Sir, yours faithfully,

Osmotherly, Nov. 30th, 1911. H. B. LUARD.

To the Editor of THE LANCET.

SIR,—Although thoroughly in accord with the professed object of the National Insurance Bill to protect the poorer classes against the evils of sickness and unemployment, I do not for one moment think that the proposed victimisation of the medical profession will serve that purpose. Surely in the fight against disease and death it is essential to the public welfare that the medical attendant should not only be well qualified, stimulated to most strenuous effort and unrestrained by handicap, but at the same time able to earn sufficient to maintain himself and his in honest independence. These conditions, I am quite certain, would not be fulfilled under a scheme which proposes to remunerate the medical attendant at so much a head. Such a scheme, on the contrary, would rapidly diminish the present number of competent men, and offer no encouragement for them to do their best.

The system of payment per head I have had considerable experience of, and I am quite convinced that it is radically wrong and unjust to patient and medical man alike. (1) The patient must employ for a time a practitioner in whom he may have no confidence; (2) the practitioner is obliged to continue attendance for a time on a patient who may make his life miserable and injure his reputation by neglecting to follow doctor's advice; (3) many, if not most, subscribers to sick clubs think that their weekly payment entitles them to call on their medical officer at any hour and for the most trivial ailments; (4) encouragement may be given to malinger; and (5) temptations to practitioners to scamp their work. These are a few of the evils pertaining to clubs paying capitation fees, and so far as I can see these deplorable evils are going to be accentuated by the proposed Act.

Therefore I thoroughly agree with the movement for demanding (1) complete liberty of choice between patient and practitioner; and (2) payment for services rendered and *not* per head. Contract practice on the lines of the National Deposit Friendly Society, however, is not quite in harmony with my ideas of sound and honest practice. Its moderate scale of fees might be accepted for poorer patients and modified for those in better circumstances, but it would be difficult, if not impossible, to draw a hard-and-fast line of income, as a curate, clerk, or small shopkeeper with £160 per annum might not be so well off as a mechanic with £2 per week. I am, Sir, yours faithfully,

JOHN DUNLOP, L.R.C.P. & S. Edin., &c.

Walthamstow, Dec. 8th, 1911.

To the Editor of THE LANCET.

SIR,—I am directed by the Salford and Broughton medical unions, which societies include practically every medical man practising in the borough of Salford, to forward to you a copy of the resolutions which were carried without a dissentient voice at their meeting held in Salford on the evening of Dec. 5th.—I am, Sir, yours faithfully,

STANLEY HODGSON,
Honorary Secretary, Salford Medical Union.

Salford, Dec. 6th, 1911.

This meeting is of opinion that the provisions of the National Insurance Bill as finally drafted do not incorporate the six cardinal points to which the profession unanimously pledged itself. That they do not secure effectual means whereby the practical working of the Bill can be carried out in absolute conformity with the principles of these six points. And therefore the Council of the British Medical Association should at once call upon all members of the profession to decline to form a panel or to undertake any duties which the Bill proposes to assign to them.

This meeting expresses its strong disapproval of the action of the Council of the British Medical Association and demands its resignation forthwith.

To the Editor of THE LANCET.

SIR,—I am a new member of the British Medical Association, having joined only a short time after the introduction of the National Insurance Bill. I have no personal acquaintance with the members of the Council, and I do not even know Mr. Smith Whitaker by sight. But I have been an interested student of the work done both by the Council and

the medical secretary since the Bill was printed, and as such I could scarcely fail to notice the conspicuous ability displayed in the various documents issued by them, and also in their negotiations with one of the keenest intellects of the present day.

I therefore look upon the appointment of Mr. Smith Whitaker as a happy augury for our future under the Bill. His unrivalled knowledge of the profession and the conditions of practice in all parts of the United Kingdom; his special experience in insurance problems; and his tact, ability, and genius for administration and organisation, as shown in the high state of efficiency to which he has brought the British Medical Association, mark him as the man best of all suited for this high and important position. I think few would gainsay the assertion that if the choice had been given to the profession to elect its own man Mr. Smith Whitaker would easily have headed the poll. That being so, I think it is rather unfortunate that unworthy motives should be attributed to the Council in connexion with this appointment and the negotiations with the Government, and on this matter I am entirely in agreement with the views expressed in the leading article in your current issue (p. 1642). I fear this is hitting below the belt. The special representative meeting gave the Council the mandate to negotiate with the Chancellor of the Exchequer and also to use every influence with the Members of the House of Commons with a view to amend the Bill so that the six cardinal points could be secured to the profession. On what points can critics of the members of the Council indict them? What are the specific charges of failure brought against them on any one of those points? In considering the matter from this standpoint I think a careful perusal of the Bill, as amended in Committee, is highly advisable. It is with valid reason contended by the Council that the Bill in its amended form will enable the profession to obtain all those points, and, I believe, too, that any impartial legal tribunal would quickly come to the same conclusion.

For example, if the medical men in any administrative area, through their directly elected Local Medical Committee, decide that they will not accept service under the Act on the *per capita* system of payment, then payment for work done can be equally as well secured them by the present provisions of the Bill. If they in the same manner fix a minimum rate of wages above which they will not attend insured persons in that area the Bill enables them to have their way on this point also. Few, indeed, seem to grasp the true significance of those Local Medical Committees with their statutory right of being consulted by the Local Insurance Committees *according to regulations issued by the Insurance Commissioners* (the italics are mine). Truly those Committees are a splendid victory for the Association.

Then with regard to the free choice of doctor, we hopefully look to the deputy chairman to see that the Harmsworth amendment will not long remain either a grievance to the profession or a menace to real free choice. For if the regulations cannot assure this, then the Commissioners have the power vested in them to vary or alter the provisions of the Act so that it will work smoothly. Therefore I think we can feel quite easy on the point. Similarly, in regard to the early actuarial figures of 4*s.* or so for medical attendance, it should be made known at once that no such absurd figure can even be discussed by us. And in this regard, does anyone think that this most astute politician, Mr. Lloyd George, who nearly wrecked his health in getting this measure through, would ruin his reputation, destroy his party, and lose his popularity by passing a health insurance scheme that could only be worked by blacklegs? Or to think that Mr. Smith Whitaker would dishonour us and himself by taking office on such conditions! The thing is too absurd to seriously discuss. I certainly prefer to consider his appointment as a friendly act towards us, and as foreshadowing that the regulations, which he will have such a large share in framing, will amply satisfy the just demands of the profession and thereby give the public a truly efficient and national medical service.

Our one and only danger now is disunion, and it is therefore deplorable that some branches should seem to be inclined to adopt separatist tactics. That road leads to ruin and certain disaster, and to those whose thoughts turn that way no better recommendation could be given than to advise them to read the "Battle of the Clubs" (published by THE LANCET), and the report on "Contract Practice." This will put them in a frame of mind to reflect on what we have been, and what we might be again if we abandoned our present splendid organisation and destroyed that unity which now makes us so powerful.

I am, Sir, yours faithfully,

Mile End, E., Dec. 10th, 1911. M. S. HARFORD.

To the Editor of THE LANCET.

SIR,—Your attitude on this question is only what might be expected from the antecedents and prestige of our leading journal.

But apart from the utter unsuitability of the contract principle in its application to medical practice, there is in the provisions of the Bill one point which in its special bearing on the general practitioner seems to have hardly gained the attention it deserves. I speak of the transference of dispensing out of the hands of the practitioner into the hands of the dispensing chemist. Now, at first sight this seems a step in the right direction, for the compounding of drugs is not rightly our province, and in widely different circumstances I should welcome the change. But the chemist has about as much right to *prescribe*, as the doctor to *dispense;* and over the counter, and in the little room behind his shop he already has trespassed long on what is undoubtedly our legitimate domain, so that to transfer into his hands our only set-off against him is a manifest injustice.

I have throughout declared my adherence to the system of payment according to services, and on no account whatever shall I withdraw. The inherently vicious principle of contract, which the action of those who should know better has alone enabled the Chancellor to retain, ought to be rejected. This Bill is *not ours*, though it might be from much that has been done and said about it; it is Mr. Lloyd George's; and if he is unable to reduce to practice the principle which alone can make it acceptable to us, then, so far as we are concerned, there should be an end to the whole matter.

I am, Sir, yours faithfully,

Rotherham, Dec. 7th, 1911. HUBERT H. B. WILKINSON.

To the Editor of THE LANCET.

SIR,—In my letter to you in to-day's issue of THE LANCET a slight error has crept in which unfortunately quite alters the meaning of what I intended to convey. The item, "Mr. Lloyd George is *not* fully convinced that £4,500,000 is inadequate to achieve his beneficent objects," should read, "is *now* fully convinced."

I am, Sir, yours faithfully,

J. P. WALKER, M.D. Durh., D.P.H.,

Dec. 9th, 1911. Assistant County Medical Officer for Hants.

To the Editor of THE LANCET.

SIR,—The advocates of "payment for work done" seem to think that this method will ensure that we shall be paid a fair fee and that we are much more likely to get adequate remuneration than by the capitation payment. But I venture to think that when the fees are suggested they will be far from acceptable to the majority of practitioners and that a reaction will set in. The National Deposit Society is often referred to, but their statistics are quite misleading, and their fees ridiculously low. This society deals mostly with a class that has a low sickness-rate—the small tradespeople and the well-paid artisan. And the whole aim of this society is to cut down medical attendance by drawing from the member's deposit for payment

If payment for attendance is adopted in the insurance scheme there will be no inducement to curtail medical attendance, or to discourage malingering. Coddling and encouragement of imaginary diseases and trivial complaints would abound. The bills would startle the Insurance Committees and extra grants be applied for everywhere. Then the ratepayers would cry out and another method of payment would be insisted on. The medical profession would be accused of being "out for fees" and be discredited in the public eye. In this system there is less obvious inducement for the practitioner to warn the drunkard, restrain the gourmand, advise the careless, or improve the hygienic conditions than there would be in a capitation payment. The immense labour of book-keeping and sending in sick reports and bills would be a very serious matter.

Our profession has always been content to do a great amount of gratuitous and underpaid work, and we must recognise the fact that it will always be so. We get our

compensation in many ways. The money value of medical services cannot be estimated. All we ask for is a decent income. We can never expect any Government to guarantee all our ordinary fees for attending people under the income-tax limit or under the hoped-for £2-a-week limit. And this is what the advocates of "payment for attendance" are asking for. In "capitation" payment it is said that we take all the risk, and that in excessive sickness we should be the losers. But we must not forget that this cuts the other way, and in times of less sickness we get the same pay. Moreover, in localities with excessive sickness an extra grant could easily be made. We must remember that the capitation rate must vary in different districts unless allowance for mileage be an extra.

One of the great objections of "payment per attendance" is that the tariff of fees will tend to spread to private practice. I object to any fixed fees above a minimum. We must retain our freedom to charge what we think is a proper fee and not be bound to a scale. Contract practice is so associated in our minds with underpayment and unpleasant conditions that the name itself creates a great prejudice. But if we get better pay and are controlled by a body on which we are represented, and, moreover, if no individual bargaining is allowed and everything must be done by a Local Medical Committee elected by the profession, I fail to see any objection to it. At all events, it has got a firm hold all over the country and many are satisfied with it. No combined effort has been made to abolish it.

Can we blame the Chancellor for inferring that the system is so ingrained in our practice that a continuance, under better conditions, would be acceptable to us? Can we wonder if he asked his actuaries to work out the cost on a 6*s*. per head basis? In what other way could he have estimated the cost of his scheme? He has stated that the cost of medical attendance is unlimited. He knows that it will cost much more than 6*s*. But a low estimate must be made as in the case of Old Age Pensions, or the Bill would not go through. The Insurance Committees will know where they are if they pay on a capitation system. They would be content to pay a good fee per head rather than run the risks of the "per attendance" system. A fee of 8*s* 6*d*. per head and an extra 6*d*. for drugs would, according to my statistics for the past four years of club patients, pay in a country district. The fear that a capitation basis would encourage unnecessary calls upon the medical man will be no more real than it is at present, and every medical man knows how to stop that sort of thing, though it may take a year or two to educate the people up to the point of coming at proper hours. Some pointed admonition and combination among medical men would soon lessen the evil. It is a well-known fact that in certain districts where the medical men have protested against night calls there are very few of them. Even if an extra fee be paid for night calls every medical man would prefer to be without them.

In conclusion, I wish to emphasise that it is quite time that this controversy was settled, and that a definite decision was arrived at. For many months a special investigator has been collating statistics on contract practice and other matters. Surely he must have formed some ideas as to the "capitation" *versus* "per attendance" system? Let us settle this question and devote ourselves to other urgent matters. If we do not, I can see dissension in our ranks. In the Division of the British Medical Association in which I reside we are about equally divided on the question, and I believe it is so all over the country. I tremble to think what will happen when the Divisions have to decide this matter. It is far better to come to a general agreement. If all the arguments seem to favour a capitation fee, it is entirely owing to the fact that we have allowed this system to become established so strongly that it is impossible now to adopt any other. I am, Sir, yours faithfully,

Buckingham. ARTHUR E. LARKING.

To the Editor of THE LANCET.

SIR,—It is disappointing to find any doubt in the minds of medical men as to the policy of the British Medical Association in concurring in Mr. Smith Whitaker's appointment as Insurance Commissioner. I hope that after a little reflection the whole profession will feel unmixed satisfaction at this appointment.

Two things must be remembered, both of which, indeed, are recognised in your article of this week. First, there was to be a Medical Commissioner in any case. Is it better to have Mr. Smith Whitaker or Dr. X. Y. Z., whose attitude towards the Act might be nondescript or wobbly? Secondly, the sole and only *raison d'être* of the Medical Commissioner is that the views of the profession may be freely and ably represented on the Commission which will have the control of many important details in the working of the Act. I am not a member of the British Medical Association, but a comparatively slight personal acquaintance with Mr. Whitaker has taught me that when he has made up his mind he is not lightly swayed from a course of action. The Government has seen enough of him in recent months to know this; it cannot imagine that it will silence such an opponent by appointing him to a position which has been created on purpose that the very views he has already repeatedly stated may be officially represented. To seriously put forward the "bribery" theory is an insult to the intelligence of both the Government and the medical profession, even more than to the character of the new Commissioner.

The Association has technically departed from its position; but would it have been more tactful, more prudent, or more helpful to the profession had it objected to Mr. Smith Whitaker accepting the appointment? I feel that both Mr. Whitaker and the profession are to be heartily congratulated on an appointment which is also creditable to the Government's desire to hear the doctors' side.

I am, Sir, yours faithfully,

Norwood, S.E., Dec. 8th, 1911. S. W. CARRUTHERS.

To the Editor of THE LANCET.

SIR,—I am instructed to forward you the enclosed copy of a letter which has been sent by the Broughton Medical Union to the Members of Parliament for Manchester and Salford.

I am, Sir, yours faithfully,

R. B. FLETCHER, Hon. Secretary.

Manchester, Dec. 5th, 1911

The Broughton Medical Union.

DEAR SIR,—I am instructed to forward you the following copy of a resolution carried unanimously at a special meeting of the above union held on Dec. 1st, 1911.

That the Broughton and Salford Medical Unions, embracing practically all the registered medical practitioners in the county borough of Salford, earnestly request you to record your vote against the third reading of the National Insurance Bill as the six cardinal demands of the British Medical Association have not been embodied in the Bill.

Yours faithfully,

Manchester, N., Dec. 4th, 1911. R. B. FLETCHER, Hon. Sec.

To the Editor of THE LANCET.

SIR,—I have had sent to me by the honorary secretary of the Lambeth Division of the British Medical Association a series of circulars, asking me to become a member of that body, and to guarantee a sum in the future, with a proposed immediate payment of £1, towards a fund to carry on their struggle in connexion with the Insurance Bill, and finally threatening to brand me as "an enemy to the profession" if "I persist in refusing to commit myself to a definite statement of the profession's policy." I have written declining to agree to their requests. Is the policy of the British Medical Association "the profession's policy"? I doubt it very much. I consider the policy of the British Medical Association in connexion with the Insurance Bill anything but determined or satisfactory. It is a dallying policy, and their sanction to the appointment of their medical secretary to the post of "Deputy Chairman of Insurance Commissioners" before the six cardinal points they demand are conceded, stamps their policy as a "betrayal of trust." As to guaranteeing a sum in the future, I am not in a position to do so, if so inclined, and the threat to brand me as "an enemy to the profession" is most unjust, and amounts to nothing less than coercion. There is no more strenuous opponent of the Bill, as at present framed, than myself, and I have done, and will continue to do, all in my power to prevent it becoming law. I have brought before my patients my views on the subject, as you will see by the enclosed copies of notices placed in my surgery. I have asked each working man with whom I have come in contact for his opinion of the Bill, and, without exception, all expressed dissatisfaction—mostly in strong language. Under the Bill I should be compelled to give unsatisfactory work to my patients, and thus do away with any feeling of confidence

they may have had in their doctor. Those who accept office under the Bill must sooner or later realise that they are greater enemies to the profession than any who at present refuse to sign away their independence of action.

I am, Sir, yours faithfully,

ROBT. SAUNDERSON.

Rodney-road, Walworth, Dec. 11th, 1911.

*** Mr. Saunderson's statement concerning the Bill, posted in his surgery, is a vigorous plea for that freedom of relations between medical man and patient which he considers will be destroyed under the impending legislation.—ED. L.

To the Editor of THE LANCET.

SIR,—"Rural Practitioner" says he is absolutely convinced that the *per capita* system of payment is far and away the best and most "lucrative" in a rural district. Well, I have had 20 years' experience of a country practice and I am absolutely convinced that this system is "rotten to the core," bad for the doctor, and worse for the patient. It may under certain circumstances be the most lucrative system (though I think the word lucrative in this connexion is a peculiarly inappropriate one), but this is a matter of minor importance. Payment for work done, with proper safeguard against its possible abuse, is better for doctor and patient, though not necessarily better for the doctor's pocket. It means better work, and if the people of England and the leaders of the Friendly Societies could only be made to realise this all our difficulties would vanish.

I am, Sir, yours faithfully,

T. CUMING ASKIN, M.D. Dub.

Alderton, Woodbridge, Suffolk, Dec. 12th, 1911.

To the Editor of THE LANCET.

SIR,—I have been instructed by the Rossendale Medical Society to tender you their best thanks and appreciation for the kind way in which you have opened the columns of your journal to members of the medical profession in connexion with the National Insurance Bill.

I am, Sir, yours faithfully,

E. W. FALCONER, Honorary Secretary.

Stacksteads, Bacup, Dec. 6th, 1911.

To the Editor of THE LANCET.

SIR,—For nearly six months I have held myself in check and refrained from airing my views on the Insurance Bill in a letter to THE LANCET. It has been quite a struggle week after week to read the outpourings of others and myself keep silence. Whatever its intentions, I have all along disliked the Bill. I think it will upset my practice and land me in all kinds of troubles without giving me the least benefit in return. I have a mixed practice with some club work. I don't like the clubs, but they are useful. I object on principle to Friendly Society control, but I make the best of it. I regard it and club patients as necessary in my professional life, but I have a strong objection to extending the club system, under compulsion by Act of Parliament, to a large number of the patients of small means who are now upon my private list. The booking and collecting of small accounts is a nuisance, and there are many bad debts, but I prefer private patients. Moreover, if I give up dispensing for my smaller patients I shall have to discharge my dispenser, and perhaps lose that dispensing for my better class patients from which at present I derive part of my income. Again, the saleable value of my practice, in which I invested all my capital some years ago, will certainly diminish. Thus, from every point of view, I think the Bill detestable. I do not want it, and I never asked for it.

But when I hear all this commotion about insisting upon the "six cardinal points" and refusing to work if they are not all granted, I feel obliged to ask my colleagues whose work runs on the same sort of lines as my own (and there must be a vast number of them), do they realise the full meaning of each of these cardinal points for which they say they are so willing to strike? I am thinking in particular of "free choice of doctor," which seems to be the only demand which was immediately and willing granted by the astute Chancellor, and indeed the only point which he has substantially conceded.

I cannot imagine why we asked for this "free choice"—or why we allowed it to be made a "cardinal point." The Act will take so much away from me, why should it also rob me of my one little vested interest? With all their manifest drawbacks these clubs are now mine own and yield an assured income. With "free choice" they and the rest of my lower middle-class practice will be open to competition from all sides. Of all the silly things that have been noisily said and quietly accepted this "free choice" chatter seems to me the silliest.

The whole scheme is unpalatable. But why all this talk of "six cardinal points" when one at least of them has never been realised or even discussed? This is my first and only letter. We must know exactly what we mean to strike for before we talk of striking. At the present moment we are in a bad way, but with a little clear thinking and some sensible leadership we may yet pull through.

I am, Sir, yours faithfully,

Dec. 10th, 1911. RADIX.

To the Editor of THE LANCET.

SIR,—Surely it would have been more diplomatic and of much more service to the profession had Mr. Smith Whitaker refused the post of deputy chairman until the six cardinal points put forward by the British Medical Association had been granted.

Would it not have been better if the Council of the British Medical Association had sent to each member a circular explaining matters, and allowing them to discuss with their fellow members the offer of the appointment made to Mr. Smith Whitaker instead of the one sent excusing their having advised his acceptance of the post with such undue haste?

I am, Sir, yours faithfully,

Dec. 11th, 1911. TOWN PRACTITIONER.

To the Editor of THE LANCET.

SIR,—Having been for some 18 years a bookkeeper to the medical profession both in London and the provinces, I venture to think I can in a measure speak on some aspects of the Insurance Bill, shortly, it is feared, to become an Act. Despite all that has been said, it is doubtful if the profession fully realises the extent of the injury that this Bill may do to their practices. Most practices in which I have been engaged as bookkeeper relied to greater or less extent on the patients paying 3*s.* or 3*s.* 6*d.* per visit, and the male members of this class (with a certain number of women and domestic servants, both male and female) will now be turned wholesale into State-club patients paying 1*d.* or a little more per week. A glance at many ledgers will prove the havoc likely to result. This, however, is not all. In certain districts where Friendly Societies are grouped together and employ one medical man solely there is a provision in the Bill by which this grouping shall still continue, and if the Friendly Societies attract a large number of the State-club patients many patients will leave their present medical man who will receive nothing in return.

Only those who have worked in large club practices can realise what the profession will lose, not only financially but in standing, in return for very hard work. It is for the profession to have nothing to do with the Bill as it now stands.

I am, Sir, yours faithfully.

Dec 11th, 1911. ALIQUIS.

ELECTION OF DIRECT REPRESENTATIVES ON THE GENERAL MEDICAL COUNCIL.

To the Editor of THE LANCET.

SIR,—I wish to thank most sincerely those who voted for me at the last election as Direct Representative on the General Medical Council. I think I may almost call them my personal friends, as owing to circumstances which are not necessary now to detail, those who voted for me were directly or indirectly influenced by old associations and the fact that I have been connected with medical reform of the General Medical Council, and elsewhere, for a long period of years.

I also take the liberty of thinking that the principle of the judge not being the accuser, however indirectly, is a right one. All the Direct Representatives are now the nominees

of the British Medical Association, and as such will doubtless either have to act in the dual capacity, or have to retire from the Council when cases of great interest to the profession are brought before it.

I am, Sir, yours faithfully,

Plymouth, Dec. 4th, 1911. GEORGE JACKSON.

SANATORIUM TREATMENT FOR CHILDREN.

To the Editor of THE LANCET.

SIR,—Speaking on this subject at Cambridge in 1880, more especially with reference to hip disease, the late Mr. Timothy Holmes said [1]:—

> Who has not seen with profound sorrow poor children bandied about from one out-patient room to another, getting splints which only very imperfectly immobilise the joint or receiving injunctions to "keep at rest" which the surgeon knows cannot be carried out, till the limp becomes agonising pain and the patient is taken into hospital and allowed a little rest in bed? Then after a few weeks he is found to be occupying a bed which can be better employed; and his pain having for a time subsided he is turned out again. Possibly this process is more than once repeated, and then abscess forms; the joint is found to crepitate; and the surgeon probably knows that if he keep him in again for a few weeks and send him out relieved the disease will recur in a worse form; and so he recommends excision. I do not say that the surgeon is wrong in his advice under the circumstances, but I do say that the circumstances show our general hospitals to be places where chronic morbus coxarius can hardly be treated successfully.

Mr. Holmes died in 1907, and in an obituary notice the above passage is referred to with the painful comment that "the protest would be almost, if not quite, as much justified to-day as when it was uttered more than a quarter of a century ago."[2] The same year that the children lost Mr. Holmes they gained the Education (Administrative Provisions) Act of 1907, which gives the local education authorities power "to attend to the health" of the children.

When you, Sir, were asked as to the meaning of this you replied that "under these provisions we are of opinion that any county council may establish children's hospitals and convalescent homes at the seaside, provided they obtain the approval of the Board of Education."[3] Here, then, at last was the chance for the children, but the recent report of the chief medical officer of the Board of Education goes far to destroy this hope. After quoting Section 13 (which confers the power) the report (p. 124) goes on to say that—

> The power conferred by the section is not indiscriminate or promiscuous. In matters of construction it is necessary to consider the whole scope and purport of the Act, or series of Education Acts, in which the section occurs. From such a consideration it is reasonable to suppose that Parliament intended (*a*) that the powers of treatment under this section should be used for children who are in attendance at public elementary schools, and that therefore children whose state of health necessitates absence from school without any hope of returning, or whose state is such that they can only be effectively dealt with in permanent institutions other than schools, should be regarded as outside the scope of this section; (*b*) that the treatment supplied should be carried out in intimate connexion with the system of education and with the school; (*c*) that the maladies and conditions for which treatment is provided under this section should primarily be either such as are capable of amelioration in connexion with school life, or are conditions which are, generally speaking, characteristic of school children. Though the wording of the section is extremely general, it is in the interests of sound administration that these three considerations should be borne in mind.

This interpretation of the Act is probably not made without legal assistance; but it must be remembered that the only authoritative interpretation of an Act of Parliament is the decision of a judge, and further that on three important occasions recently the opinions of the law officers of the Crown have been at variance with those of the judges. With respect to the intentions of Parliament it may be here mentioned that when this section came up for discussion in the House of Commons it was pointed out that it would enable local education authorities to establish hospitals, and an amendment was moved; yet the amendment was withdrawn and the section passed as it stood, and still stands.[4]

When a child is absent from school on account of ill-health the attendance officer calls, and if the child is well enough orders, under threat of prosecution, that he be taken to be examined by the school doctor; if he be not well enough to go the school doctor, as I understand, does not go to see him; the child is excused from school attendance, his name is removed from the school register, and his existence possibly forgotten. Instead of this I submit the authority should instruct their doctor to go and see the child, and ascertain if he is under medical care, and if so, whether the medical attendant considers the circumstances are favourable to adequate treatment; very possibly the child cannot be sent to a sanatorium on account of the weekly charge the institution makes, and which the neighbourhood is too poor to raise; under these circumstances it would seem clear that the local education authority should exercise the power it possesses of paying in whole or in part for the child. It is true this can only be done with the consent of the Education Department, but there is no reason why the local authority should not play its part and leave the responsibility of veto where the law has placed it—at Whitehall.

If voluntary arrangements are, as they are said to be, inadequate, the above is the only way in which these children can be properly treated; the Poor-law is only for the destitute and the sanatoria of the Insurance Bill do not yet exist.

I am, Sir, yours faithfully,

Devonshire-place, W., Dec. 9th, 1911. WALTER EDMUNDS.

THE DIAGNOSIS AND TREATMENT OF URINARY TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—My attention has been called to an interesting address to the Harveian Society on the above subject by Dr. Samuel West, and published in your issue of Nov. 11th, p. 1318. He claims that the disease is difficult to diagnose in the early stage. In this I fear I cannot agree; and with regard to treatment he practically advocates a do-nothing policy, completely contrary to the teaching of modern surgery, and to a considerable extent based upon the belief, not supported by facts, that renal tuberculosis is in the great majority of cases bilateral early in the history of the disease. And in the last paragraph he says: "All that I wish now to do is to protest against regarding the removal of a tubercular kidney as an operation to be lightly decided on. It is a very grave act, requiring the most serious consideration and in all cases involving grave risks. The very ease and success with which the mere operation can now be done renders this caution, I think, the more necessary. The question is not whether the operation can be safely and successfully done, but what will be the condition of the patient afterwards, and how far his chances of life will be altered for better or worse." Every careful surgeon will accept this general statement of opinion, but he will also remember that in the present position of renal surgery there is as great responsibility in refusing an operation as in advising one, and that by adopting the former course during the time that elapses between the onset of the disease in the kidney and the invasion of other parts the surgeon may allow to escape a valuable opportunity of saving the life of his patient. Since physicians have come to appreciate the value of recognising urinary tuberculosis at an early stage the results obtained by the surgeon have greatly improved.

Now by bacteriological examination of the urine, inoculation experiments, segregation of the urine, and the employment of the cystoscope the surgeon can obtain objective proof of the presence of tuberculosis in the urinary tract long before the subjective evidence is sufficient to justify a diagnosis. "Unfortunately, when a patient is not suffering much actual pain or serious inconvenience it is difficult to convince him of the seriousness of his condition, but in all cases of primary renal tuberculosis the problem must be seriously placed before him and nephrectomy advised."[1] The diagnosis I find can often be made so early in the history of the case that the surgeon is beset with difficulty. He has proof of the presence of tuberculosis in the kidney, but the patient suffers so little, and his general health is so excellent, that it is difficult to convince him of the impending danger of his position.

Primary nephrectomy is now looked upon by urologists as the only remedy, and is resorted to when the disease is known to be limited to one kidney; and this can be determined with considerable accuracy by ordinary diagnostic methods, aided by cystoscopic examination and bacteriological research. I am sorry Dr. West does not give any evidence to support his statements. I may say

[1] The Surgical Aspects of Early Renal Tuberculosis, by the writer, The Practitioner, July, 1911.

that I collected statistics of operations in all stages of the disease[2] published from 1891 to 1908, and found that during that period lumbar nephrectomy for tuberculous disease gave a mortality of 27·4 per cent. and abdominal nephrectomy 33 per cent. Now we find that when the disease is limited to one side and there is no tuberculous disease elsewhere, nephrectomy results in cure in 30 per cent., with an operative mortality of about 10 per cent. This is taking general statistics, but in the hands of surgeons of great experience the cures are in a larger proportion, and the mortality is about one-half—namely, 5·8 per cent. I may now take Walker's statistics,[3] giving the remote results in 210 cases of nephrectomy: Reported as well, 79 cases; recovered, 83 cases; cured, 20 cases; good results, 4 cases; improved, 7 cases; not improved, 2 cases; improvement not maintained, 15 cases. I think it will be admitted that these statistics convey a different impression from that contained in the remarks made in Dr. West's address.

Further, Dr. West says, "When the disease in one kidney is advanced enough to be capable of certain diagnosis the chances of the other kidney being affected too are very considerable ....." This depends, of course, upon the methods employed in making the diagnosis and the stage at which the disease is detected, but let that pass, and permit me to quote a passage from Watson and Cunningham[4]:—

> Clinical evidence of unilateral renal tuberculous infection.—The testimony of this nature upon the unilateral occurrence of renal tuberculosis is derived from, and based upon, the examinations of the urines drawn separately from each of the two kidneys, and from the facts with regard to permanency of the cures or entire absence of evidence of the existence of renal tuberculosis subsequent to nephrectomy of the kidney which is known to be invaded by it. Upon the evidence of this character, such surgeons as Krönlein, Israel, Kümmel, Rafin, Kelly, Bevan, Reynaud, Casper, and Hurry Fenwick assert that the process, at the time at which the patients were examined by them, was confined to one kidney in from 50 to 80 per cent. of the cases.

Or, taking the disease not at the stage when it should be presented to the surgeon, but when it has done its worst and has come under the review of the morbid anatomist rather than the clinical pathologist, Halle and Motz[5] found in 131 cases of renal and ureteral tuberculosis examined by them post mortem, in 89 the disease was confined to one side, in 42 it was bilateral.

I think it right to place these facts before the readers of THE LANCET to justify the position I have maintained that—

> It is to the diagnosis of tuberculosis in the early stage that we must especially direct our attention, seeing that in its later developments the aid of the surgeon is of little avail.[6]

And—

> In some instances when first seen by him [the surgeon] the disease is so advanced that little can be attempted to stay its progress or to mitigate the suffering of the patient, while in other cases the malady is still limited in extent, and much may be done by early surgical intervention. Even a few years ago renal tuberculosis was looked upon as almost a certainly fatal malady, but now that new and more exact methods can be employed in detecting the disease in the early stage, the surgeon is not uncommonly placed in a position to advise and to carry out operative measures with considerable hope of success.[7]

I am, Sir, yours faithfully,

Glasgow, Dec. 2nd, 1911. DAVID NEWMAN.

A SPHYGMOGRAPHIC METHOD FOR THE ESTIMATION OF SYSTOLIC AND DIASTOLIC BLOOD PRESSURE.

To the Editor of THE LANCET.

SIR,—In Mr. S. G. Longworth's letter in your issue of Dec. 2nd it is stated that "according to Dr. George Oliver and others, the point to take [for the reading of the diastolic pressure] is that at which a distinct change in the intensity of the sound occurs, which is generally pronounced and limited to 1 or 2 mm. of the scale." So far as I am concerned, your correspondent is under a misapprehension. The later results of my observations, which appeared in the *Quarterly Journal of Experimental Physiology*, March 3rd, 1911, support the view of Ettinger, Gettings, and others to the effect that the disappearance of the throb on release of air-pressure indicates the minimum arterial pressure. I said: "If we accept the lower limit of throb as the indicator of the true diastolic or minimum pressure, then the range of throb furnishes three readings of the arterial blood pressure—namely, those of the minimum, the mean, and the maximum pressure. ..... Observation shows that the mid-reading coincides, as a rule, with the optimum oscillation of the mercurial column, which has hitherto been accepted as the indication of the diastolic pressure. We do not, however, know what the maximum oscillation as an indicator of arterial blood pressure actually does signify, and it is not improbable that further observation will show that it represents more nearly the mean arterial pressure rather than the true diastolic pressure." The diastolic pressure definitely afforded by the disappearance of the throb has not yet been studied and appreciated sufficiently in clinical work.

I am, Sir, yours faithfully,

Farnham, Dec. 10th, 1911. GEORGE OLIVER.

THE PRACTICE OF MEDICINE IN BRITISH COLUMBIA.

To the Editor of THE LANCET.

SIR,—As I think considerable misapprehension exists in the British Isles in regards to the conditions of medical practice prevailing here, I venture to call attention to certain facts in the hope that the information may be a help to others. Before I arrived here I was firmly convinced that my Edinburgh qualifications would be sufficient to enable me to practise medicine here. I thought I had merely to hang up a blass plate and the patients would come flocking in. This is, however, not the case. In British Columbia and in Alberta, as I believe in all the provinces in the Dominion of Canada, there is a medical examination. This is open to any medical man or woman who has studied medicine for a minimum of four years at a recognised medical school and obtained his diploma. Nobody is allowed to practise in British Columbia or in Alberta until he or she has passed this examination.

It would appear that almost complete ignorance prevails at home with regard to this examination, and it is entirely erroneous to consider it as anything but a severe test of knowledge. In British Columbia the examination lasts for the better part of two weeks, and papers are set in all the subjects in the average medical course, with the exception of biology and physics. Clinicals and orals are conducted in medicine and surgery, as well as an examination in practical bacteriology and in clinical methods. The examination is a thoroughly fair test of knowledge and is practical, as the examiners are, without exception, either specialists in the subjects in which they examine or general practitioners.

In May there were 42 candidates, of whom 19 failed, and this month 62 made their appearance, and 23 were unsuccessful. In each examination several candidates with qualifications from the British Isles were unsuccessful. In both May and this month an Edinburgh graduate failed to qualify, and two or three London College men were among those rejected. Now these were in every case quite good men, and the reason of their failure was owing to their ignorance of prevailing conditions. They had read or been told that the examination was a mere formality, and had regarded it as such. For my own part I arrived in British Columbia two full months before the examination last May, and devoted the time to reading. Despite this fact, and the experience I had gained as a house physician and surgeon in Edinburgh, I was by no means certain of the result until the lists appeared. In Alberta the conditions are similar, although there are no oral and clinical examinations.

We have here a wonderful country and one that will loom largely in the future history of the world. It is undoubtedly a land of promise, and conditions of practice are very much more favourable than in the British Isles. "Old Country" graduates are always welcome here, not only among the general public, but also among our Canadian colleagues, and it seems to me a pity that men who are undoubtedly skilled practitioners should fail at an examination when a little extra preparation would entirely alter the result.

Although this is in every way a very favourable country in which to practise medicine, money is not made with quite that rapidity which many expect. A certain amount of capital is necessary. In Vancouver, with any reasonable success, $1500 should be made in the first year. In the smaller towns and in the Kootenay and the Cariboo fees are

larger, and most of the doctors make their expenses from the start. In any case practitioners should be prepared to wait for a few months at least, and it would be well if this fact were understood. Then we would not be faced with the spectacle of an "Old Country" graduate arriving with some $170 as his entire assets. Even this might be overcome if he succeeded in satisfying his examiners, but in default it means a nearer acquaintance with a pick and shovel or other form of manual labour.

In conclusion, I would say that I shall at any time be delighted to answer any communication I may receive regarding this undoubtedly wonderful country with its endless opportunities.

I am, Sir, yours faithfully,

GEORGE GIBSON, M.D., M.R.C.P. Edin.

724, Robson-street, Vancouver, B.C., Nov. 14th, 1911.

*** We may mention, in regard to the above interesting letter, that in an article on "The British Medical Man Abroad"[1] it is stated that an examination has to be passed before a qualified person is admitted to the Register in British Columbia and Alberta.—ED. L.

THE STATISTICS OF THE BENENDEN SANATORIUM.

To the Editor of THE LANCET.

SIR,—In a recent publication, "Sanatoria for the People,"[2] the authors, Mr. C. H. Garland and Dr. T. D. Lister, have made some very definite statements regarding the results of the treatment of tuberculosis in the Benenden Sanatorium. They state (pp. 16 and 17) that "as a matter of accumulated experience, the successful cases wherein the disease becomes completely arrested are about 70 to 80 per cent. of the admissions," and further that "with patients able and willing to continue their working lives under simple hygienic modifications, 80 per cent. are found to be still on full work and wage-earning two years after discharge; and as knowledge spreads among the working classes, as shown by the German insurance experience, the lasting nature of the recovery tends to increase. Statistical evidence will be found in Appendix II."

I have carefully examined the figures given in Appendix II., and so far as I understand them can find none which appear to provide the above percentages. It is obviously of the highest importance that data in publications of this kind, directly intended to influence public opinion, should be so expressed as to be intelligible to the layman. May I therefore as a layman ask the authors to explain how they reach these percentages?—I am, Sir, yours faithfully,

DAVID HERON.

Galton Eugenics Laboratory, University College, Gower-street, W.C., Dec. 12th, 1911.

THE PRESCRIPTION OF TUBERCULIN.

To the Editor of THE LANCET.

SIR,—Mr. P. W. Squire's memorandum attached to the letter of Sir R. Douglas Powell and Dr. P. Horton-Smith Hartley appears to confuse rather than settle the issue raised by your reviewer. The review stated that instead of representing the small initial dose of T.R. by "0·000,000,001 cubic centimetre," "a more convenient method would seem to be to express the amount in fractions of a milligramme." Your reviewer will doubtless make his meaning clear, but workers with tuberculin would understand this to mean vulgar fractions of a milligramme of tubercle bacilli, not fractions of a milligramme of T.R. liquid, as assumed by Mr. Squire.

The point raised by your reviewer is sufficiently important to be illustrated by experience. I have made an examination of the 1000 last orders received by Messrs. Allen and Hanburys for T.R. and B.E. (the two forms of tuberculin to which the alternative method of stating the dose applies), and find that on 912 orders the dose is stated in vulgar fractions of a milligramme of tubercle bacilli, and in 23 cases in decimal fractions of a cubic centimetre of the concentrated liquid. On all Messrs. Allen and Hanburys' labels the dose is stated in both forms—e.g., "New Tuberculin T.R. 0·000,001 c.c. (1/100,000 milligramme T.B.)"; physicians can therefore employ the system they prefer without trouble. Although precedence is given on the label to the decimal method of stating the dose now used by the makers of Koch's tuberculins, on 91·2 per cent. of the orders received the doses are written in vulgar fractions of a milligramme of tubercle bacilli. I think it must therefore be conceded that the latter is the more popular and presumably the more convenient way. I am, Sir, yours faithfully,

F. W. GAMBLE,

A PLEA FOR AN AMENDED CLASSIFICATION OF UTERINE FIBROIDS.

To the Editor of THE LANCET.

SIR,—Permit me space to make a suggestion as to the amendment of the usual description of fibroid tumours of the uterus in regard to their position in the uterine wall. Hitherto hard and soft fibromata of the uterine wall have been described as submucous, mural, and subserous. The submucous fibroid is occasionally pedunculated; the subserous is more often so. The foregoing classification was strictly anatomical. What I now propose is a classification which, whilst being anatomical, is in every sense of the term clinical as to pathology and treatment. I will now briefly explain.

Most uterine fibroids are placed either inside or outside the centre of the middle coat, which is occupied by the larger blood-vessels supplying the uterine wall. The classification I now propose is to locate every uterine fibroid, anatomically and clinically, either on the inner or the outer aspect of the central vascular zone of the middle coat. Anatomically, therefore, one would speak of an "inner" and an "outer" fibroid, sessile or pedunculated, in strict relation to the central vascular zone of the middle coat of the uterus, because this classification, from a clinical point of view, can be shown to be important. I have so often seen a uterus which is the subject of multiple fibroids have all of them confined either to the inner or the outer side of this vascular zone of the middle coat, that I begin to think that there must be some developmental rule why this should be; because if a uterus is found to have a so-called subserous fibroid and this is accompanied by other smaller ones they will almost invariably be found on the peritoneal side of the central vascular zone of the middle coat. The same applies to the submucous fibroid; seldom does one see fibroids on both the inner and the outer side of the vascular zone of the middle coat simultaneously. The clinical pathology of the proposed classification of these tumours is interesting and shows a strong contrast in their behaviour.

No gynæcologist of any experience but must have seen a case of severe hæmorrhage from a fibroid uterus, endangering life and often causing death, yet after hysterectomy or post mortem, on laying open the uterus, no point or punctured blood-vessel can be found anywhere to account for the hæmorrhage, the uterine mucous membrane over the tumour appearing merely congested. In conversation with Mr. Shattock, of the Royal College of Surgeons Museum, he very aptly described this hæmorrhage as "uterine epistaxis." This hæmorrhage or epistaxis in my experience is only caused by fibroids situated in the uterine wall on the *inner side* of the central vascular zone of the middle coat of the uterine wall, the salient factor not being that the fibroid is a so-called "submucous" fibroid, but that it is "internal" to the vascular zone in the middle coat of the uterus. How the hæmorrhage is caused can be briefly explained. The fibres of the middle coat outside the vascular zone and all the fibres of the outer coat when the fibroid has reached such a size that by their contraction they can compress the whole vascular circulation against the fibroid, cause an intense venous stasis of the mucosa, more especially over the tumour. And so we have established a hæmorrhage very much like that which occurs in the stomach after gastro-duodenostomy and other abdominal operations; in other words, a true epistaxis which may or may not be fatal. This *inner fibroid* is also liable, in the event of a miscarriage occurring in the early months of an existing pregnancy, especially if the placental site be over the tumour, to become

displaced inwards as a partially pedunculated tumour by uterine contraction, be presented at the os and cause death from hæmorrhage unless its presence and clinical significance are recognised and the tumour rapidly enucleated and delivered per os. A medical colleague recently informed me of a patient of his who died from hæmorrhage from this very cause in a well-known London hospital for women.

Uterine fibroids, on the other hand, situated "external" to the central vascular zone of the middle coat of the uterine wall, do not give rise to uterine hæmorrhage, whether sessile or pedunculated, for very obvious reasons, because contraction of any muscular fibres external to them does not compress the venous channels in the middle coat. Reverting to "inner fibroids," my experience leads me to class them as to their liability to produce hæmorrhage by their situation in the uterine wall. Fibroids situated below a line joining the insertion of the Fallopian tubes are more liable to produce hæmorrhage of the kind described than fundal fibroids. Of those situated below the insertion of the Fallopian tubes, lateral cornual tumours are most prone to cause hæmorrhage, because the efferent vessels of the uterus emerge here; then tumours in the cervix and anterior wall, then tumours in the posterior wall; and lastly, and least, fundal tumours.

Finally, from the clinical-operative point of view, the classification I propose as "inner" and "outer" fibroids has a practical bearing on treatment, because the probability is that where a uterus is the subject of an "outer fibroid," any others will all be found external to the vascular zone of the uterus, and can on abdominal section be removed by myomectomy without fear of hæmorrhage. This will permit us to leave the uterus, perhaps enabling the patient to become subsequently a happy mother. On the other hand, uterine fibroids situated internal to the vascular zone can be removed without much hæmorrhage by dilatation of the cervix, with or without splitting of the anterior lip, by blunt dissection out of the uterine wall with the fingers and dissector or by previous *morcellement*, followed by enucleation and delivery, which I have repeatedly successfully done, even treating tumours as much as 5 lb. in weight. This latter procedure also leaves the woman with the power of subsequently becoming a mother.

I am, Sir, yours faithfully,

F. W. FORBES-ROSS, M.D.Edin., F.R.C.S. Eng.

Harley-street, W., Nov. 29th, 1911.

DREAMS.

To the Editor of THE LANCET

SIR,—In an annotation in this week's LANCET upon Mr. Havelock Ellis's book on dreams you quote the late Sir Samuel Wilks's remark that "the dreamer merely forms a mental picture, and the description of it he calls his dream." To my mind, however, the question how we form "a mental picture" still waits for a reply. Each individual among us, as the late Sir Francis Galton remarked, is a composite cellular creature made up of a bi-parental half, a grand-parental quarter, and the residue of definite fractional parts of earlier forebears. We also believe that the chromosomes, "the individual entities" as Mr. C. E. Walker calls them, "are distributed from cell generation to cell generation, from parents to offspring in a manner that coincides exactly with the behaviour of the individual characters." ("Hereditary Characters," p. 213.)

Now as regards dreams during "the solemn watches of the night," I have often recalled visions of my parents, seldom of my paternal grandfather, more frequently of my maternal grandfather, whom I personally resemble in many respects, and occasionally of my dead son. According to biometricians, there are twice as many molecules (or atoms or ions) in my body that have directly sprung from my two parents as there are others originating in my four grand-parents. The chances of a parental atom knocking at the portals of my sleeping brain, and in that way exciting a "mental picture," are therefore many times greater than are those affecting a grand-parental atom. This suggestion, I fancy, accounts in my case for the repeated dreaming of parents. It would be interesting to know whether my experience coincides with that of others. I have been led into this train of thought through another experience. On two or more occasions I have indulged in a hearty meal of under-done beef late in the evening, and have gone to rest shortly afterwards. I have notes of two dreams after such a meal, written soon after the event. In each dream I was crossing an open space, when suddenly savage-looking cattle obstructed my path, and I took to my heels, to awake in a cold sweat, with an uncomfortable sensation in my head and—stomach! Is it possible that here we have the Machiavellian stimulus of a semi-devitalised ox-cell upon my dormant cerebrum? I am, Sir, yours faithfully,

Hove, Dec. 9th, 1911. W. AINSLIE HOLLIS.

UNIVERSITY AND COLLEGE REFORM.

To the Editor of THE LANCET.

SIR,—May I state with regard to your short account of the meeting of the Fellows and Members of the Royal College of Surgeons of England, published in THE LANCET of Nov. 25th, that I did not venture to "prophesy" what the Royal Commission on University Education in London would or would not do. I just warned the Council *not* to rely solely upon the side issues (to them) of the numerous University regulations or the extraneous representations of the Polytechnic or Royal College of Science or other bodies, and which the Royal Commissioners were chiefly considering. No doubt my motion with regard to the M.D. and M.B., B.S. degrees and the Conjoint Examination Board of the Royal Colleges has occupied, and still does occupy, the attention of the Council on behalf of the Fellows and Members—a vital point for their future welfare; and so far there was no actual need to carry my division on the motion over again, since it was passed before on a similar resolution. But what is, is! And the Council would do well either at once to obtain the power of this Act themselves, or when they go before the Commissioners to let them understand they intend to seek these particular rights of examining for a degree, under their compact with the University of London and under the Act of 1898, but which lately the University of London has so carelessly and selfishly denied to them and to her partner. There is nothing to prevent this action, nor to hinder the Council from moving for a confirmatory Act.

The differences between the above views and those of the present President, Mr. Godlee, under the discarded Jenner and Westminster schemes, may certainly be judged to be reconciled. Indeed, it would be auspicious if his tenure of office coincided with his being able to pre-eminently carry out what he and other reformers, *and now the University and college reformers*, have aimed at on the common ground of a degree basis instead of the obsolete licences.

I am, Sir, yours faithfully

Dec. 7th, 1911. H. ELLIOT-BLAKE.

*** Mr. Elliot-Blake is advocating the granting of degrees by the Colleges in conjunction with the University.—ED. L.

PRESSURE-PAIN SENSIBILITY IN FACE AND TONGUE.

To the Editor of THE LANCET.

SIR,—In connexion with your annotation on this subject in THE LANCET of Nov. 18th, may I point out that two of the statements made by Dr. Maloney and Dr. Foster Kennedy are in excess of ascertained facts? They write thus of the hypoglossal nerve:[1] "It is probably a pure motor nerve in its peripheral course"; again, "The hypoglossal appears to be a purely motor trunk." They also write of "the purely motor function of the seventh nerve after it leaves the Fallopian canal." But all that their excellent research established on these two points was that these two nerves contain no pressure-pain sensibility fibres in those parts of their course. We are almost certain, however, that the main twelfth trunk and the six facial branches peripherad of the stylo-mastoid foramen contain postural afferent nerve fibres for the tongue muscles and the facial muscles respectively, because Professor Van Gehuchten found by experiment[2] that in the rabbit the peripheral seventh nerve at the stylo-mastoid foramen contains afferent fibres which rise in some of the cells of the geniculate ganglion; and also Professor Sherrington found in 1894[3]

[1] Brain, September, 1911, pp. 23 and 26.
[2] Journal de Neurologie, 1898.
[3] Journal of Physiology, vol. xvii., p. 255.

that the hypoglossal was one of several nerves mentioned by him "which contain abundance of fibres from sensory ganglia."

In my opinion, the present position of our knowledge, which is, however, incomplete in several directions, justifies the following provisional conclusions: (1) all the pressure-pain sensibility fibres of the tongue enter the organ by the communicating branches between the lingual branch of the mandibular nerve and the anterior part of the hypoglossal nerve; (2) possibly a few postural afferent fibres also enter by that path; (3) most, if not all, of the postural tongue muscle afferents enter the organ by the main hypoglossal trunk, probably from the second and third cervical dorsal root ganglia; (4) all the pressure-pain sensibility fibres for the facial muscles enter by the communicating branches on the face between the fifth and the seventh nerves; (5) some of the postural afferent fibres for these muscles probably also enter by these branches, in witness whereof I may refer to Dr. Harvey Cushing's well-known findings of postural facial palsy after Gasserianectomy in some cases; (6) most of the postural afferent fibres to the facial muscles rise in cells of the geniculate ganglion, and enter the muscles by the six peripheral facial trunks.

I have in this letter touched merely the fringe of this subject. I hope to show subsequently that all these points, and many more, can be studied, and in a large measure settled, by properly planned experimentation reinforced occasionally, as opportunity occurs, by pathological study.

I am, Sir, yours faithfully,

LEONARD J. KIDD, M.D.

Haverstock Hill, N.W., Dec. 2nd, 1911.

SANITATION AND SEWAGE DISPOSAL AT LEEDS.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

LEEDS holds a good position among our largest towns so far as vital statistics are concerned. Perhaps the most remarkable figures are those that relate to the mortality from scarlet fever. In the "seventies" the death-rate from this disease occurred in the proportion of 1·11 per 1000, in the "eighties" it fell to 0·68 per 1000, in the "nineties" to 0·19 per 1000, while the average from 1900 to 1909 was only 0·11 per 1000. Yet it can hardly be said that vast public works have been pressed forward so as to better the sanitary conditions of the city.

Back-to-back Houses: the Rent and the Death-rate.

The building of back-to-back houses has, unfortunately, not been radically abolished, yet Dr. L. W. Darra Mair's report to the Local Government Board (Cd. 5314, 1910) on back-to-back houses was very conclusive. This official document gives the results of investigations in Leeds and 12 other industrial towns of the West Riding of Yorkshire. Care was taken to separate houses in good condition and in healthy localities from those less favourably situated. It was found that where back-to-back houses are built in continuous rows, even though they are of a relatively good type, the death-rate from all causes is from 15 to 20 per cent. higher than in ordinary houses which have windows both in front and behind. Such is the advantage of through ventilation and the purifying effects of light on both sides of the houses.

The inhabitants of back-to-back houses suffer especially from diseases of the chest and defective growth in childhood. The aged and the young are the principal victims. But the rents of such dwellings are one-fifth cheaper than ordinary houses of equal size and affording the same accommodation. The increase in the death-rate is about in the same proportion as the decrease in the rent paid for back-to-back houses. In other words, where back-to-back houses are replaced by houses with through ventilation a death-rate of 20 per 1000 per annum would be reduced to a death-rate of 16 per 1000 per annum. Of those who die in back-to-back houses, 20 per cent.—one-fifth, or 1 out of 5—are brought prematurely to the grave to save 4*s.* in the £ paid for rent.

In 1893 the Leeds Corporation obtained permission to allow the building of more back-to-back houses. The injury resulting from this mode of construction was not then as fully appreciated as it is to-day, nevertheless it was well known that such houses were comparatively unhealthy. But then there was the saving of money, so the corporation was left free to decide whether under certain conditions and restrictions builders should be allowed to construct yet more and more back-to-back houses. The chief hope now is that under the Housing and Town Planning Act of 1909 this harmful practice will be definitely stopped.

Wholesale Testing of Drains.

If the corporation is thus unprogressive in allowing such houses to be built, the sanitary authorities have displayed commendable energy in the inspection of inhabited dwellings. More than 18,000 houses are inspected in the course of the year, and this does not imply just a passing visit, but the thorough overhauling of the entire premises. Thus the air space and means of ventilation are noted, and the drains are not only outwardly examined but tested. Such methods revealed last year no less than 3955 defects or leakages in drains. This is really most important, because the fact that the closets are kept clean and that there is no noticeable odour does not prove that the drains are absolutely water- and air-tight. The scavenging department also seems to be very active, and altogether it appears likely that the low death-rate enjoyed at Leeds is due rather to careful attention to details than to any large sanitary measure or scheme.

Pollution of the River Aire.

So far as any great undertaking is concerned, Leeds is best known on account of its extensive experiments and works for the disposal of sewage. The last Census shows that Leeds has a population of 443,568 and stretches over an area of 21,572 acres. Considering that there are also many industries and no large river or sea front where the crude sewage can be discharged, it will be seen that it must be very difficult to dispose of the sewage satisfactorily. It was in 1848 that sewers were first built at Leeds, and then the crude sewage was allowed to flow into the small river Aire at Knostrop, which is about two miles south-east of the town-hall. This practice continued until 1870 when an injunction was obtained, and the corporation of Leeds was ordered to stop the nuisance. Four years were now devoted to experiments, and then settling tanks were built. By mixing chemicals with the sewage a sludge was obtained and a clearer and cleaner water thrown into the river. But if this was an improvement the results were still far from satisfactory. In 1893 the West Riding Rivers Board was constituted to act on behalf of those who were interested in the prevention of the pollution of rivers. In the course of time, certainly not with any reckless or undue haste, but in the lapse of four years, five new precipitation tanks were constructed, and now all the tanks put together could hold six and a third million gallons. Far more remarkable than this extension of an old system were the numerous and valuable experiments then made in the bacteriological treatment of sewage. The corporation has published in volume form a full account of these experiments which were conducted by Colonel T. W. Harding and Mr. W. H. Harrison, M.Sc. This appeared in 1905, and together with the Leeds experiments in general has been the subject of much discussion and comment. It would be somewhat out of date to travel over the ground again, but some of the main points ascertained may be briefly recalled.

The Aerobic Treatment of Sewage.

In contact beds effective aeration must be secured. The oxidising surface of small is greater than that of large filtering material. But, on the other hand, the smaller the filtering agent the more thoroughly does it retain all suspended matter, and thus the filter is very soon clogged. The coarser the material the longer will it remain serviceable. Now the great point ascertained at the Leeds experiments is that at least half the suspended matter in sewage cannot be dissolved by bacterial action. Further, if it is allowed to clog up the filter a fungus will grow upon it and complicate matters. A coarse filter will let mineral and inorganic matter pass through and only retain what can be digested—that is, transformed by bacteriological action. Therefore it was found that filtering for clarifying purposes should be the second and not the first operation. The experiments went on to prove that it was necessary to pass the sewage through a fine screen and then on to a coarse filter. In normal dry weather this sufficed to oxidise the sewage, and though it was still thick and contained

much suspended matter it was not putrescent. The sludge from sewage collected after passing through a coarse filter could be dried in the open without causing nuisance. This is a rapid aerobic treatment. In a quarter of an hour sewage could be passed through the screen, the coarse filter, then a finer clarifying filter, though a process of precipitation instead of the second filtration would require much more time.

The need of rapid and economic action may antagonise the claims of science that the purification should be reliable and absolute. Whether the sewage is thrown on land or on artificial filters neither medium must be overworked. There must be periods of rest for ploughing the land or for removing the accumulations and washing the materials of the filter. When fresh air is plentifully supplied the aerobic organisms rapidly and inoffensively destroy animal substances; but if the transformation of vegetable substances is similar it requires a much longer time, and this is especially the case with woody fibre, such as paper pulp. The present sewerage works, however, have not yet bacterial beds in operation.

The Importance of Screening Sewage.

A good deal of time and trouble can be saved by removing from the sewage the larger particles of suspended matter. They choke the filters, and for the most part cannot be transformed or digested by bacterial action. At Leeds, especially as a consequence of the local industries, there are large quantities of fibre and wool in the sewage. Last year the discharge of waste water into the sewers by the different trades amounted to a little over 3,500,000 gallons in the 24 hours. Of this more than 2,000,000 gallons came from piece scouring, wool scouring, and dyeing. Something like 20 per cent. of the average dry weather flow of sewage comes from the trades and industries of the city. To prevent some of the difficulties this would cause there are actually 88 settling tanks on the manufacturers' premises, where the waste water is submitted to a preliminary treatment before it is allowed to flow into the public sewer. Fifty-two of these tanks are under the direct control of the corporation. When, with the courteous assistance of the medical officer of health, Dr. J. Spottiswoode Cameron, I was enabled to visit the sewage works, the first thing examined was the screens used to prevent large particles of suspended matter reaching the tanks and filtering-beds. There are two screens 10 feet wide, made of strong bars with a wire mesh between, only 5/8ths of an inch apart. Revolving rakes, driven by an electric motor, automatically remove what is retained by this screen. It was black-looking stuff, but it is valuable, for the farmers are very eager to get as much as possible. It has also been advantageously used as manure by market gardeners.

Clarifying the Sewage.

The sewage arrives at the works by gravitation, but after passing through the screens is lifted 16 feet into tanks by a couple of pumps. Two dynamo pumps of 52 and 75 b.h.p., each driven by Delaval steam turbines, are also in action to supply power for the screens, the chemical precipitation machinery, and for lighting the works by electricity. Thirty million gallons of sewage can be lifted out of the main collector into the tanks in the course of a day. From the pumps the sewage is divided between two grit-pits. The heavy matter that settles at the bottom of these pits is lifted and removed by a Priestman grab or digger and a travelling steam crane. The sewage is now allowed to flow into a central chamber where it is mixed with milk of lime, for this is more expeditious than lime water. The lime is broken into fine dust, and there are ingenious contrivances to ensure that the quantity of lime shall be regulated according to the quantity of sewage to be treated. After this the sewage, distributed in different tanks, is allowed eight hours for sedimentation. From the tanks the effluent goes by the main channel to a gauge chamber, where it is measured by an automatic recorder, and finally discharged into the River Aire below Thwaite Mill weir.

Utilising the Sludge.

The total amount of sewage treated in the 12 months ending March 31st, 1911, was estimated at 5,929,754,000 gallons. This is a daily average of 16,290,535, or about 38 gallons per day per head, from a population of 427,500. The working expenses amounted to £2820, including the consumption of 3840 tons of coal at 10*s.* a ton. Nearly five million gallons of water were evaporated. The cost of lifting the sewage works out at 4·25*d.* per million gallons per foot lift. The screen stopped 1527 tons of garbage, or 4½ tons of large particles were arrested per day and prevented from clogging the sewage works. This is equal to 5 1/6th cwt. for each 1,000,000 gallons of sewage, and the cost was 1*s.* 1*d.* per million gallons of sewage. The amount of grit extracted from the pits near the entrance by the crane and grab amounted to 1755 tons, or 4 tons 16 cwt. per day, making 6 cwt. of grit per million gallons of sewage. For precipitating purposes, 929 tons of lime were used at 12*s.* 8*d.* the ton, and in the proportion of 10 parts of lime to every 100,000 parts of sewage. The total cost of chemical precipitation was £1098, or 3*s.* 8*d.* per million gallons of sewage.

The sludge from the tanks amounted to 120,365 tons, of which 91·10 per cent. is water, which is afterwards reduced to 86·6 per cent. by further treatment. After this the sludge is passed into presses, and the result for the year was the production of 36,786 tons of sludge cake. For the treatment of the sludge 1 per cent. by weight more lime is added. Altogether the cost of dealing with the sludge was £3035, or 10*s.* 3*d.*, per million gallons of sewage treated. This makes the cost of the sludge cake amount to 1*s.* 8*d.* per ton. It still contains 59·7 per cent. of water. The mineral residue is 23·0; the volatile matter, 16·8; the fixed carbon, 4·2; the total nitrogen, 0·61; and the total phosphate as calcium phosphate, 0·98 per cent. The making of sludge cakes has not proved a profitable enterprise. Only 3623 tons of the sludge cakes were sold and for the modest sum of £160. The greater part of the cakes, 28,459 tons, were conveyed on a narrow gauge railway to some low-lying land recently acquired in this neighbourhood by the corporation. Here it was tipped over to an average depth of six feet and then covered with a layer of soil. It is stated that the low land which is thus being raised to a higher level will be used for public gardens and not for private dwellings.

The Effluent Obtained.

The analyses made compare the crude sewage with the effluent after treatment. The results are in parts per 100,000. The crude sewage, giving the average of the whole year, showed: Suspended solids, 60·7; soluble solids, 108·8; albuminoid ammonia, 0·663; oxygen absorbed in four hours, 12·23. The effluent from the tanks of this sewage after treatment contained: Suspended solids, 7·3; soluble solids, 104·1; albuminoid ammonia, 0·367; oxygen absorbed in four hours, 5·16. Much better results are anticipated when, as embodied in the sewerage works extension scheme, bacteria beds are constructed. The great difficulty has been to obtain the necessary land. In 1900 the corporation, finding nothing closer at hand, bought 1880 acres 13 miles away near Selby. But then four years later the Selby urban district council, in spite of opposition from Leeds, obtained powers from Parliament to bore for water-supply and storage close to the land which the corporation of Leeds wanted to use for new sewerage works. Adjoining the existing Knostrop sewerage works there is land that would do admirably for the extension of the sewerage works, but the owner would not sell his land for such a purpose. Towards the end of 1904, however, his successor withdrew opposition. In 1908 Parliament passed a Bill by which the corporation was able to acquire 600 acres of land adjoining the Knostrop sewerage works from this estate, and there the bacteria beds will be constructed. In the meanwhile the corporation had been again prosecuted, and was ordered by the late Mr. Justice Grantham, in July, 1907, to remodel its works at Knostrop, so that the suspended solids in the effluent from the tanks in dry weather should not contain more than 11 parts per 100,000. It is these reconstituted works that I visited and have described. The analyses given above show that Sir William Grantham's instructions have been faithfully carried out. But it will be still more interesting to see the results when the land newly acquired is fully utilised.

The Workers at the Sewerage Works.

At present there are 70 workmen engaged at Knostrop. On inquiring about their health I was assured that some of them had been employed on the sewerage works for 20 years and had not suffered a day's illness. For the most part they are middle-aged men, and though in the immediate vicinity of sewage, they are constantly in the open air. The chief fear is blood poisoning. Therefore antiseptic dressing is

kept ready to hand, and great care is taken to use it even for slight cuts. Somewhat rough washing convenience and a mess-room are provided, together with a heating oven. Each man has a locker where his food can be kept clean and the dust and the flies cannot get to it. The men bring their food with them and are glad to be able to warm it up. Thus the essentials are provided, though it must be remarked that not a thought has been bestowed on relieving the roughness and dreariness of the mess-room. The scientific treatment of sewage is so essential to the well-being of the community that it is perhaps not too much to ask for a little attention to the comfort of those who labour all day long at the sewerage works.

BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

Third South Midland Field Ambulance.

THE new headquarters of this ambulance were opened on Saturday, Nov. 25th, by Earl Beauchamp. They are situated in Kingsdown, Bristol, and provide excellent accommodation, including a spacious drill-hall, sergeants' mess, lecture-hall, commanding officer's room, officers' room, quartermaster's stores, a demonstration room, wagon sheds, and a harness room. Earl Beauchamp congratulated the corps on this evidence of the interest taken in the Territorial movement in the west country, and said they owed a great debt to Colonel A. W. Prichard and Colonel J. Paul Bush for their work of organisation.

Bristol General Hospital.

The work of building the new wing has begun; at least, the workmen are demolishing a large warehouse to make room for it. This warehouse, the property of the hospital, was purchased some years ago to make extension possible when the occasion arose. Its replacement by the new wing will make the circle of hospital buildings surrounding the main courtyard complete at last, for it has hitherto occupied the gap between the pathological block and the main body of hospital premises.

Bristol Hospital Sunday Fund.

At the annual meeting of the committee administering the collection and distribution of the Lord Mayor's Hospital Fund for Bristol, it was announced that a sum of £1887 13*s.* 9*d.* had been collected in 1911, the bulk of which had been divided among the medical institutions of the city as follows: Royal Infirmary, £739 10*s.*; General Hospital, £620 10*s.*; Children's Hospital, £232 13*s.*; Eye Hospital, £110 10*s.*; other institutions, £107 3*s.* Mr. William Garnett was appointed honorary treasurer in the place of Mr. E. J. Swann, who has retired. The Lord Mayor (Mr. F. W. Wills) said he hoped it would be possible to raise £2000 at least in 1912.

The Royal Hospital for Children, Bristol.

A meeting of the Ladies' Auxiliary in connexion with the Children's Hospital, Bristol, was held last week. The report stated that during the past 12 months 290 ladies had canvassed 253 districts for the funds of the charity and nearly £900 had been collected by them.

Mussels and Enteric Fever.

At a meeting of the St. Thomas (Devon) rural district council held on Dec. 8th a letter was read from the Derby council, stating that a case of enteric fever which had occurred in that town had been attributed to mussels brought from Lympstone, and asking the district council to take steps to prevent the mussel beds from being polluted. After a considerable discussion, during which it was stated that the pollution of the river Exe, where the mussel beds are situated, was principally due to the sewage of Exmouth, it was decided to refer the matter to the Lympstone parochial committee.

Death of Mr. George Arthur Slack.

Mr. G. A. Slack died at his residence, The Lodge, Uffculme, Devon, on Nov. 18th, in his sixty-fifth year. He was the son of the late Mr. T. T. Slack, of Paignton, and received his medical education at Guy's Hospital, London. He qualified as M.R.C.S. Eng. in 1886. Shortly afterwards he commenced practice at Uffculme and married the daughter of the late Rev. T. C. Tanner, vicar of Burlescombe. Mr. Slack was well known and very popular in Uffculme and the district, and much regret is felt there at his death. The funeral took place at Uffculme on Nov. 22nd in the presence of a large gathering, which included several of the local clergy and members of the medical profession.

Dec. 12th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Liverpool School of Tropical Medicine: Banquet Celebration of Foreign Expeditions.

AT the invitation of Sir W. H. Lever, the chairman of the School of Tropical Medicine, a banquet was held at the Adelphi Hotel, Liverpool, on Dec. 6th, to meet Professor Newstead on his return from the sleeping sickness expedition to Nyasaland, and Dr. Harald Seidelin on his departure to Yucatan, Mexico, on a yellow fever investigation expedition. Owing to having contracted a chill, Professor Newstead was, unfortunately, unable to be present, but forwarded a written communication which was read during the evening. Among the guests were Professor Sir Ronald Ross, K.C.B., Sir Edward D. Lawrence, Sir Alfred Haslam, Sir Edward Evans, Dr. Richard Caton (formerly Lord Mayor of Liverpool), Dr. J. W. W. Stephens (Walter Myers lecturer in tropical medicine), Dr. E. W. Hope (medical officer of health), and Mr. A. H. Milne, C.M.G. Sir William Lever proposed the toast of "Professor Newstead's Expedition and that of Dr. Harald Seidelin." He first of all expressed his great regret at the enforced absence of Professor Newstead. He remarked that it had always been the good fortune of the Liverpool School to attract to itself the very best men in the cause of scientific research. He thought Liverpool ought to have facilities for the treatment of sleeping sickness not to be equalled in any other part of the world. The trustees of their late revered chairman (Sir Alfred Jones) had intimated that they would come to their assistance, and in addition to better accommodation in Liverpool it was proposed to establish a laboratory on the West Coast of Africa where investigations into tropical diseases might be made on the spot, and so enable them to curb and check, and possibly to finally exterminate, this dreadful scourge. He took this opportunity of congratulating Sir Ronald Ross (Sir Alfred Jones professor of tropical medicine), and Mr. Milne (the secretary of the school) upon the honours recently conferred upon them by the King. Dr. Harald Seidelin, in responding to the toast, expressed his gratitude to the late Sir Rubert Boyce for having made it possible for him to become connected with the Liverpool School of Tropical Medicine. In Yucatan he himself had been afflicted with yellow fever, and it was his object to establish the principal points in regard to the mosquito parasite. He had demonstrated the parasite in the blood, and he now hoped to find it in the living state. He also hoped to find the parasite in the mosquito, and to find some new means of treatment of yellow fever. He expected to make important entomological investigation, if there were time. As yet he could not promise any great results, but he would do his best. The toast of "Research into Tropical Diseases," proposed by Sir Edward Lawrence, was responded to by Sir Ronald Ross, who said that Liverpool had become one of the greatest centres of medical research, and anyone who contributed to the movement would be making a gift to humanity. The chairman suggested (amid applause) the sending of a telegram to Sir William MacGregor, congratulating him upon the first report of the Queensland School, and also a message to Dr. H. W. Thomas, who was on the Amazon investigating yellow fever, conveying Christmas greetings.

Fatal Case of Anthrax in Liverpool.

The deputy coroner recently held an inquiry into the death of a workman in the Mersey Docks and Harbour Board's Wool Warehouse, which occurred at the David Lewis Northern Hospital on Dec. 2nd. The deceased had been employed at the warehouse for the last 10 years. His duties were to deal with bales of Persian wool, which had been imported into Liverpool by a ship from Bombay. Shortly after 6 P.M. on Nov. 29th he drew his landlady's attention to a pimple on his neck, and said to her, "That's anthrax." He went to

the hospital, where the lesion was dressed, and returned home. He returned to the hospital on the following day and was advised to become an in-patient, where an operation was subsequently performed. In spite of this he died on the following day. A verdict of "Death from anthrax poisoning" was returned by the jury.

Chester Infirmary: Improvement Scheme.

The board of management of the Chester Infirmary has decided to set in motion a scheme for extending and renovating the infirmary, which is estimated to cost about £25,000. The abandonment by the Chester town council of the electricity works as a site for the refuse destructor was reported, and in consequence the board unanimously agreed to proceed with its scheme. The plans of the extension and the reports from the medical committee will be submitted to the board of management at its annual meeting in January, 1912.

Dec. 12th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Policy of the Medical Profession in Scotland.

THE profession in Edinburgh is deeply concerned about the Insurance Bill, to the exclusion of other topics, and this feeling is reflected in the lay press, to which many letters have lately been contributed by medical practitioners. In the *Scotsman* in particular an important discussion is in progress with regard to the attitude to be adopted by the profession in Scotland towards the Bill. The council of the Edinburgh branch of the British Medical Association on Dec. 8th passed resolutions urging all members to remain loyal to the Association during the present crisis, and determining that in the event of the Bill becoming law the Association should continue to insist on its demands being carried into effect through the Local Medical Committees. The meeting was also attended by representatives from most of the other Scottish branches of the Association. In a letter in the *Scotsman* of Dec. 11th Dr. William Russell and Dr. A. Logan Turner contend that the wage limit should from the first have been made "the centre and citadel of the medical position." Now, however, the controversy between the Chancellor and the profession has been transferred to one between the Local Insurance Committees and the medical men. Under these circumstances it lies with the Local Medical Committees to see to it that whatever predatory instincts may be manifested by the Local Insurance Committees should be restrained and opposed. The writers claim that the canvass of the different areas in Scotland has been so complete that it is now only necessary for the men who have pledged themselves to adhere to their pledges to insure that service under the Act will be such as the profession has continuously insisted upon. In conclusion, they declare that it is impossible for the profession in Scotland to wash its hands of the Act and decline to set up Local Medical Committees, because many local Scottish organisations of the Association have already decided to carry on the fight in the local insurance areas to be constituted under the Act. Dr. William Craig, in a letter in the same issue, criticises various points in the policy adopted by the executive of the Association, and maintains that the "quasi-strike resolution" has postponed definite decision, and that consequently the profession is now being led on against its wish "into a position from which it will have difficulty in retreating and in maintaining its ranks." Dr. J. Stuart Ross suggests in the same issue that the way out of the difficulty, so far as Scotland is concerned at any rate, is that proposed by Dr. Gibson. Let a Scottish National Committee be formed of men universally trusted by the profession, and let its first task be to investigate this alleged evidence of "a multiplicity of potential blacklegs." The profession in Scotland would then, Dr. Ross believes, be in a position to decide whether to refuse to enter into any negotiations, and wait for the breakdown of that part of the Act which refers to medical benefit, or to form Local Medical Committees to inquire at any rate what are the best terms to be obtained under the Act, as interpreted by the Insurance Committees and Commissioners. A large number of men wish to adopt the first course, while the second is recommended by the Association.

Aberdeen Doctors and the Family Medical Fund.

A circular has been sent to every medical practitioner in Aberdeen by the local branch of the British Medical Association, which states that at a meeting of the division held at 29, King-street, on Nov. 27th, the secretaries reported that the circular recently issued with reference to the abolition of the Family Medical Fund, and avoidance of competition for Friendly Society Lodges, had been signed by every practitioner in Aberdeen and suburbs. It was unanimously resolved that every practitioner undertaking Friendly Society work for 1912 should do so on the following terms:

I accept the appointment for the year 1912, unless the National Insurance Bill, now before Parliament, becomes an Act, and becomes operative within the year, in which event this contract shall cease.

Dec. 12th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Insurance Commissioners.

THE appointments to the Insurance Commission are better than rumour led one to expect. The chairman, Mr. Glynn, is known to be a liberal and fair-minded man and a good man of affairs. He is a solicitor, and has been for several years chairman of the Galway county council. Mr. Kinnear, the deputy chairman, is energetic and still young; he has been connected with insurance business all his life, and is at present President of the Insurance Institute of Ireland. Dr. W. J. Maguire, the medical Commissioner, is senior physician to the Mater Infirmorum Hospital in Belfast, and was formerly a lecturer on clinical medicine and examiner in medicine in the Queen's University, Belfast, and examiner at the National University of Ireland. The appointment of a woman Commissioner was not expected, but the Government has been well advised in securing the services of Mrs. Dickie. She has been for several years an inspector of boarded-out children for the Local Government Board, Ireland, and it is chiefly due to her exertions that the boarding-out system has proved a success.

The Milk Commission.

The Milk Commission has held several sittings in Dublin, and has examined, among others, Sir Charles Cameron, Professor McWeeney, Professor W. H. Thompson, Dr. O'Donoghue, Mr. Andrew Watson, M.R.C.V.S., and Lady Dunleath. Sir Charles Cameron stated that milk brought into Dublin from the country was more frequently at fault than milk produced in the city, and he urged the necessity of giving medical officers of health the power of tracing milk to its source. Professor McWeeney spoke of the relation of typhoid fever to milk-supply and of the danger of typhoid carriers. He suggested that all persons engaged in the handling of milk should be required to submit to the Widal test. He urged also that tuberculous cows should be slaughtered. Professor Thompson spoke of various substitutes for fresh milk when the latter cannot be got, and he recommended dried milk as the best. Lady Dunleath strongly advocated the use of goat's milk as a substitute for cows' milk, and referred to her experiments in the introduction of two varieties of goats, by crossing which with the old type a greater bulk of superior milk was produced. Dr. O'Donoghue gave disquieting evidence as to the condition of the dairy-yards in the northern part of County Dublin, of a large part of which he is medical officer. Of 70 dairies in his district 20 were not fit for the keeping of cows. In three recent epidemics of typhoid fever the cause was directly traceable to milk infection. Moreover, there was great laxity in the administration of the Dairies and Cowsheds Order, and no attention was given to the clothes or general condition of the persons handling the milk.

A Medical Assessor to a Judge.

In a case brought before him last week for the recovery of medical fees from the executors of a deceased patient, the Master of the Rolls postponed the hearing until he could have the assistance of a medical assessor. Sir Charles Ball ultimately sat with him throughout the case. Judgment was given for the full amount claimed.

Feeding of School Children.

For some time past there has been discussion in Dublin concerning the undue length of the school hours in the primary schools. In most cases children sit, or, worse still, stand, in class from 9 30 in the morning to 3 in the afternoon, with a break of half an hour in the middle of the day for lunch and exercise. The poorer children have no lunch, and have, therefore, to fast from early morning till late afternoon. The system is thoroughly unhygienic, and many suggestions have been made that the school day should either be shortened, or be broken into a morning and an afternoon session. A Ladies' School Dinner Committee has been formed in Dublin, which attempts, by subscriptions from the public, to provide midday dinners for the poorer children. A deputation from this committee waited on the corporation a few days ago to ask for a grant from the city funds. In Ireland, however, municipal authorities have no power to strike a rate for such a purpose.

The Exclusion of Medical Benefit from the National Insurance Bill.

At a meeting of the Belfast Trades Council held on Dec. 7th a resolution was passed condemning the action of the Irish Parliamentary party in excluding medical benefits from Ireland.

Medical Guild Formed in Belfast.

On Dec. 7th, at the Medical Institute, Belfast, when Dr. J. R. Davison presided over a large attendance, it was decided to form a medical guild in Belfast to include all branches of the profession. Its object is to watch carefully all movements likely to affect the interests of medical men in any way, and to take united action in regard to them. It will work in harmony with existing medical societies, but will deal with matters which cannot be treated in a satisfactory manner by the other societies—the Irish Medical Association, Ulster Medical Association, or British Medical Association—as at present organised. A committee was appointed, with Dr. Davison as chairman, Dr. George Elliott as secretary, and Dr. John Simpson as treasurer, to draw up the constitution and the rules of this new medical guild. The guild has forwarded its congratulations to Dr. W. J. Maguire on his appointment as Medical Commissioner in Ireland.

The Belfast Water Commissioners.

At a largely attended meeting of the Belfast Citizens' Association held on Dec. 11th a letter was read from a member of the Water Commissioners to the effect that people used too much water in Belfast, and that they had to blame themselves for its scarcity. This comment occasioned considerable amusement. There is a strong feeling that the time has arrived for amalgamating the board with the city corporation, and the chairman of this annual meeting of the Citizens' Association pointed out that the late Belfast Health Commission in its report strongly recommended that the Water Board should be amalgamated with the city corporation. It was also pointed out that this same arrangement had been advised by a special commission as far back as 1859.

Ballymena Cottage Hospital.

From the thirteenth annual report, presented to a meeting of the supporters of the Cottage Hospital, Ballymena, held on Dec. 5th, it appears that 128 patients—97 interne and 31 externe—were treated during the past year. Financially the income was £549 16*s.* 8*d.* and the expenditure £516 10*s.* 6*d.*, leaving a credit balance of £33 6*s.* 2*d.*, which is larger than in the previous year.

Dec. 12th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Illegal Practice of Medicine.

THE illegal practice of medicine unfortunately continues to find easy dupes in France. It is a singular fact that the public, although often distrustful of the properly qualified medical man and his prescriptions, has implicit confidence in irregular practitioners and readily follows their advice even when it is actually childish. At the last meeting of the Syndicate of the Medical Men of the Seine, this important association, which has about 1500 members, discussed the reasons of the present remissness in the application of measures for the repression of illegal practice. M. Levassor, to whom the syndicate had specially assigned this duty, regretfully acknowledged that these practitioners employed clever lawyers, and were using every endeavour to lead the syndicate into protracted and costly litigation. Legal proceedings of this description were not only deplorably slow, but they also required to be supported by expert testimony, the expense of which was often heavy and was not always repaid to the syndicate. It was nevertheless to be wished that the steps taken for this purpose should have some practical result in the way of putting down these abuses, which not only deprived medical men of a portion of the income which they might reasonably expect to derive from their profession, but even damaged the reputation of the profession itself, through the misunderstandings which irregular practitioners endeavoured to create in the minds of the public.

Opposition of the Students to the New Regulations for Medical Study.

By a decree bearing date January, 1909, some important changes were ordered to be made in the system of medical education, chiefly with respect to the duration of the curriculum, which was increased from four years to five. This prolongation was quite essential on account of the time required to be spent in hospital and laboratory work, a requirement designed to prevent the granting of medical qualifications on the ground of merely theoretical knowledge. Practical work in physiology, medical physics, medical chemistry, and bacteriology will, in fact, be obligatory and will be combined with theoretical instruction so as to provide experimental illustrations of the latter. Hospital attendance will extend over the whole curriculum, commencing with elementary clinical instruction and progressing through the various departments of study, so that under the tuition of the Faculty the future practitioner will have had opportunities of observing the clinical features and the treatment of all the serious conditions which he will encounter when subsequently practising on his own account. Finally, to diminish the effect of chance in the examinations the students will have a memorandum book in which will be entered the marks which they have obtained in practical work, in clinical exercises, and in previous examinations. This new decree has just been issued by the Minister of Public Instruction with the signature of the President of the Republic, but has not been well received. Medical teachers and students have requested that it should be referred back for modification, but their objections have been disregarded, as the decree has been issued after signature and the Chamber of Deputies will soon be requested to vote the funds necessary for carrying out the new scheme. This being the position of affairs, the manifestations of hostility to M. Nicolas had only just been quelled by the temporary cessation of his lectures, when turbulent scenes were again created by the first year's students on Nov. 28th, and the Incorporated Association of Medical Students resolved to carry on an energetic campaign for the purpose of obtaining from the public authorities the withdrawal of the new decree. Large posters to this effect have been displayed throughout the Quartier Latin and the first year's students have held a crowded meeting at the offices of the incorporated association. This meeting adopted a resolution to the effect that the students objected to the decree on the ground that it would be unworkable in practice and prejudicial in its action, for by extending the practical and special courses it would interfere with clinical teaching and deprive the students of opportunities for personal study; it was also incomplete because the prolongation of hospital attendance was not made applicable to all the departments of hospital work, but would, on the contrary, bring more students into wards which were already overcrowded with them. The students therefore requested that the decree should be withdrawn and referred to the Superior Medical Council; it was also decided to make arrangements for approaching the Minister of Public Instruction.

The International Sanitary Conference.

M. de Selves, the Minister of Foreign Affairs, opened the International Sanitary Conference which is being held in Paris under the presidency of M. Barrère, the French Ambassador to Rome. The idea of an understanding between

various Governments for the purpose of organising a combined defence against imported epidemics is of French origin, the first Sanitary Conference having been held at Paris in 1851. The present conference is revising the rules adopted in 1903 in order to bring them into conformity with recent discoveries as to the etiology of epidemic diseases, and enforce (1) better notification of infectious diseases, and (2) the application to shipping (with heavy penalties in case of default) of the sanitary requirements in regard to unwholesome dwellings. The conference is also recommending an improvement in the position of the medical officers of passenger vessels, officers who are ill-selected, ill-paid, and ill-provided with requisites for rendering all the services which might be expected from their knowledge and their devotion to duty.

Piroplasmosis among Horses in France.

The horses of some of the agricultural associations in the neighbourhood of the ponds of Camargue in the Department of the Gard have been suffering from a disease the nature of which has until lately remained a mystery. The principal symptom of this disease, which has a case mortality of from 80 to 90 per cent., is progressive anæmia, accompanied by pyrexia, and the attack generally proves fatal in a few months. A single proprietor has through this disease sustained a loss of about 300,000 francs. The nature of the malady has at last been elucidated by the patient researches of M. Dubois, chief veterinary surgeon of the Gard, and M. Grouzet, veterinary surgeon at Saint Gilles, in the same Department. It is caused by a parasite which multiplies in the blood of the horses. This parasite resembles the hæmatozoa found by Laveran in equine piroplasmosis, a very common condition in South Africa—especially in the Transvaal and Cape Colony—as well as in Algeria and Morocco. As in Africa, so in the Gard, the disease in conveyed by the bites of insects. The epidemic in the Gard is the first scientifically observed instance of equine piroplasmosis in France.

Presentation to Professor Armand Gautier.

On Nov. 25th the colleagues, friends, and pupils of Professor Armand Gautier held a celebration in honour of the fiftieth anniversary of his university career, and presented him with a medal and a bust of himself executed by M. Vernon and M. Theunissen. The Minister of Public Instruction was represented by M. Bayet, director of the department of higher education, who was in the chair. Successive addresses were delivered by M. Haller, president of the medal and bust committee; Professor Landouzy, representing the Faculty of Medicine; M. Lippmann, representing the Academy of Sciences, of which Professor Gautier is the president; M. Hanriot, representing the Academy of Medicine and the council of hygiene; and M. André Lefevre, representing the old pupils. Professor Gautier, who was deeply moved, expressed his hearty thanks to all those who had contributed to the success of the meeting.

Dec. 11th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Meeting of the Austrian Medical Councils.

THE yearly meeting of the delegates of all the Austrian Medical Councils has just taken place, and its proceedings on this occasion had a direct bearing on the various problems urgently requiring a decision. The proposed new series of regulations, called the Aerzteordnung (equivalent to a Medical Act), is now under consideration amongst the members of the profession, and there has seldom been a law or a legislative proposal which has evoked such a uniform opposition from the classes affected by it as this has done. The meeting of the councils has been arranged chiefly for the purpose of discussing and repudiating this unwelcome Bill, and for considering what steps should be taken for the protection of the profession against such a measure.

As has already been pointed out in this column[1] one of the chief grievances of the profession was the article which would in certain circumstances ignore the rule of professional secrecy. Since that time, however, it has become known that several other clauses have been proposed which appear to be equally inacceptable. Thus, for instance, the meeting has passed a resolution to the effect that a *numerus clausus*, such as has been proposed by the Government, is absolutely against the interests and wishes of the medical profession. This portion of the Act would introduce for towns with more than 50,000 inhabitants and for health resorts a stipulation that the number of medical men permitted to practise there should be regulated by the magistrates.

Another resolution adopted by the meeting was to the effect that practitioners should be entitled to refuse to render medical aid to certain corporations, institutes, or classes of people if such an understanding has been arrived at between a number of practitioners. This is in direct opposition to the view of the Government expressed in Section 35 of the Act as follows: "Arrangements by which a certain class of persons or a district or institute shall be excluded from receiving medical help are inadmissible and cannot bind the parties concerned." The intention of this article is to make a medical boycott of certain clubs impossible. During the last few years there have been serious disputes between the clubs and their medical officers, but the latter have hitherto been able to hold their ground owing to successful boycotting. Naturally, the profession would lose one of its most useful weapons if a boycott were made unlawful for them. For this purpose the Medical Act provides also the possibility of allowing foreign medical men to practise in Austria, and they would be allowed to do so by the Government if, for instance, a part of the Austrian medical men should declare a strike. Of course, the profession protests vehemently against this clause, and the councils have adopted a resolution condemning it. The Government is, in fact, trying to make the Act as useful for itself as possible in order to suppress the liberty of our profession and to make it subservient to Socialistic tendencies, without granting us any compensation. The meeting has sent its protest and its resolutions to the Government formulated in unmistakeable terms.

Amongst other subjects discussed was the problem of private practice by military medical officers on active service, who do not come under the scope of the regulations, and are in many respects much better off than the private practitioners. The meeting resolved to ask the military authorities that military medical officers engaged in private practice should be subject to the same regulations and laws as the civilian practitioners in the same district. Another question brought before the meeting was an old desideratum of the profession—namely, a law dealing with sanitary matters all round. This would require the creation of a special ministry for health affairs, the head of which should be a doctor of medicine. The question of dentists has also been under discussion during the last year or two. The Government intends the creation of a special class of dentists, who should be intermediate between the mere mechanical dentist of to-day and the doctor of medicine, without being surgeon-dentists. The profession has repeatedly protested against the introduction of this hybrid class of dentists, for if they were allowed it would not be possible to exclude such half-qualified men from other branches of medicine, and the effect would be that ophthalmology and pædiatrics would be invaded by opticians and truss-makers. The meeting repeated the old protest.

One of the final subjects under discussion was the formation of a medical bank which should work hand in hand with the medical insurance company already existing, and grant mortgages and loans on easy terms to medical men and corporations. An active discussion was devoted to the old but burning question of national insurance against sickness. Here, as in England, the profession insists on a certain maximum wage limit for those who will be eligible for compulsory insurance under this scheme; with us an annual income of 2400 kronen, or £100 a year, is the limit conceded by the profession, whilst the Government want the amount to be 50 per cent. more. The profession also wants the club members to have free choice of a practitioner, which, however, the clubs are stoutly refusing. These points are regarded as so important that preparations are being made to declare a strike if the above-mentioned proposals should become law in their present form.

[1] THE LANCET, Sept. 19th, 1910.

The meeting has therefore had very important questions to consider in order to protect the interests of the profession, and on the present occasion the proceedings of the meeting have received more attention from the general body of practitioners than ever before.

Dec. 9th.

NOTES FROM SOUTH AFRICA.

(FROM OUR OWN CORRESPONDENT.)

Medical Legislation.

IT is anticipated that a measure will be introduced in the course of the ensuing session of Parliament to consolidate the laws of the different provinces in the Union relating to the registration of medical men, dentists, chemists, trained nurses, and midwives, and to the practice of medicine, the sale of poisons, and the like. Some curiosity and no little anxiety are being felt as to the provisions of the anticipated measure. Shortly after the consummation of Union, delegates from the four medical councils met in Johannesburg for the purpose of considering what should be done, and to advise the Government thereon. It is understood that the delegates to that conference, after considerable debate, at length mutually agreed to a series of resolutions. For some extraordinary reason, however, the delegates pledged themselves not to divulge for the time being their proposals to the profession, and to this date the secret has been more or less completely kept. This much has, however, leaked out, that the scheme outlined by the delegates was for a central medical council with four provincial committees, the latter to be enabled to effect registration and to deal with disciplinary cases, accused persons having, however, the right of appeal to the central council. In other words, the committees were to be more or less autonomous, and in all but name provincial medical councils. It appears to have been left to the Orange Free State delegates to draft a Bill for the consideration of the Government embodying the resolutions. They consequently wrote to the Minister of the Interior and asked for the assistance of a draftsman. In reply the Minister asked for the minutes of the conference, and stated that on perusal of these he would have a Bill drafted for submission to the medical councils embodying such of the resolutions as the Government might feel they were able to accept. The minutes were forthwith forwarded to the Minister, and nothing further has been heard of the matter beyond the fact that questions as to the position have been raised at the meetings of the various medical councils. The handing over of the minutes to the Government was a most unwarranted proceeding, for the conference was not in any sense a Government Commission, and the proceedings had no business even to have been withheld from the profession. From a well-informed source it is gathered that the Minister of the Interior does not approve of the proposals of the conference, and it would not seem improbable, therefore, that when the new Medical Bill is published it will be somewhat of the nature of a bombshell. At a recent meeting of the Orange Free State Medical and Pharmacy Council correspondence was read regarding the question of publication of the minutes of the conference, but the president maintained that the sanction of the Government should be obtained before the publication of any statement regarding the matter. On the motion of Dr. Manning, however, seconded by Mr. Hewit, it was resolved that it should be suggested to the Transvaal Medical Council that the Minister of the Interior be asked to publish the minutes of the conference or the Draft Bill, as prepared by the Transvaal Medical Council, and to circularise the same amongst the members of the professions concerned.

Cape Province Medical Council.

Under the Cape Medical Acts the medical officer of health for the colony is *ex officio* a member of the Cape Medical Council. With the retirement on pension of Dr. A. J. Gregory that office has been abolished, and consequently there should really be no such *ex-officio* member on the council. It is characteristic of the procedure now in operation that notwithstanding its obvious illegality the Government has informed the council that the assistant medical officer of health for the Union, stationed in the Cape Province, has been *nominated* to the position in lieu of the medical officer of health for the Colony. Several members of the council have objected, but it is understood that the President ruled that the appointment was to be regarded as a lawful one pending the receipt of advice from the Minister of Justice, which the Department of the Interior has been requested to obtain.

Friction in the Johannesburg Hospital.

Feeling is again running high in connexion with the Johannesburg Hospital, and the dissensions between the medical staff on the one hand and the board of management on the other are rapidly reaching a stage when it will become necessary for the former to consider whether they can with dignity continue to hold office. If they resigned they could at least rely on the support of the local profession, and unless conditions improve this course will probably become necessary to secure reform. A strong feeling of discontent with the existing system of administration has been simmering for several years. The medical staff is not only inadequately represented on the board, but it is ignored whenever any vital question of hospital policy has to be decided. If the medical staff were given adequate representation on the board it is probable that much of the ill-feeling and cause for dissatisfaction would disappear. For many years in other hospitals in South Africa the same defect existed, but these mostly are now administered by boards on which the profession is represented, a reform which in nearly every instance was achieved only after a prolonged struggle. A proposal is being made to replace the native wardmaids, porters, and orderlies at the Johannesburg Hospital with Europeans, at an additional cost of £1500 per annum. One influential member is responsible for the proposal, but it was accepted readily by the board, and it was decided to request the Government to provide the money for carrying it into effect. It is not likely that the request will be acceded to.

The Pneumonia Investigation.

Sir Almroth E. Wright landed in Cape Town on Sept. 26th on a six months' engagement with the Chamber of Mines. He was welcomed by Dr. C. F. K. Murray and Dr. D. J. Wood, representing the Cape Province Medical Council, Dr. A. J. Gregory on behalf of the Chamber of Mines, and Dr. M. Hewat and Dr. F. B. Morris, the President and secretary respectively of the Cape of Good Hope (Western) Branch of the British Medical Association. Sir Almroth Wright had intended to visit the Kimberley mines before proceeding to the Rand, but he received an intimation in Cape Town that there was a severe outbreak of pneumonia in one of the mine compounds, and he consequently was unable to carry out his intention. It is to be hoped sincerely that his mission may be successful, for pneumonia is responsible for hundreds of deaths annually at the mines, and all measures taken so far have met with but little success. Sir Almroth Wright was accompanied by Dr. R. W. Dodgson and Dr. W. Parry Morgan. The former gentleman has already had considerable experience of South African problems, for he was at one time in the bacteriological branch of the Cape Public Health Department, and also has had service under the Rhodesian Administration.

The Rietfontein Lazaretto.

The Government hospital, known as the Rietfontein Lazaretto, has recently attracted a good deal of attention in the Transvaal press. This is the chronic sick hospital for the Transvaal, but it also serves as an infectious diseases hospital and a syphilitic depôt. Not only are the buildings quite unsuitable for the purposes for which they are used, but the administration of the institution has during the last few years left much to be desired, and some of the conditions which have been brought to light can only be described as deplorable. The people on the Rand have at last become fairly roused over the matter, and some remarkably strong resolutions were passed at large public meetings held in Johannesburg on Oct. 16th and presided over by the mayor of that town. The hospital is little more than a collection of wood and iron shanties located anyhow on the veldt. The various branches of the institution are not properly separated, and no attempt is made to classify patients in a proper manner. The press has, as usual, exaggerated the condition of affairs, but much of what has been alleged has, at least, a substratum of truth. It is understood that as a result of the agitation the institution is to be rebuilt. It is to be hoped that the system of administration meanwhile will be overhauled.

NOTES FROM CHINA.

(FROM OUR OWN CORRESPONDENT.)

The Revolution and Red Cross Work in China.

IN my former notes I drew a sad picture of the troublous times the Chinese Empire was passing through from flood and famine. The present state of the country from the added political upheaval is little short of chaos. No one, Chinese or foreign, no matter what his official position may be, can predict what the morrow may bring forth, and in the absence of any efficient central control the different revolutionary centres in the provinces are keeping the country in an extremely unsettled state. Some sensational news has been sent to Europe which has caused anxiety among those having relatives here. Without wishing to make any invidious distinctions I might perhaps hint that those of your readers who wish to get the most sane and sober view of affairs out here would do well to follow the telegrams and articles sent to the *Times* by its well-known correspondent Dr. G. E. Morrison, who no doubt owes something to his medical training for the calm and deliberate methods of reasoning and deduction that he brings into his journalistic calling. When the outbreak took place at Wuchang it was soon seen that neither the Imperialist army nor the revolutionist force was in possession of any adequate medical corps. Shanghai was not long in organising a party under the auspices of the Red Cross Society mainly on the initiative of Mr. Shen Tun-ho, a Chinese gentleman. This party, led by Dr. S. M. Cox, of Shanghai, assisted by Dr. Bennet and Dr. Olesen, two Chinese doctors, and 25 medical students, left for the front and has since been doing good work on the field. At Hankow Dr. J. MacWillie, of the American Protestant Mission, lost no time in getting together a Red Cross Corps which has rendered great assistance. At Peking the Central Government invited the diplomatic body to call for the services of foreign doctors to work in a "Benevolent Society" it was forming. Some hitch has, however, occurred, as the foreign Ministers wished for an understanding that any medical work undertaken would be in accordance with the recognised rules of the Geneva Convention. So far this undertaking has not been officially given, and as racial feeling is at present very bitter between Manchus (the Imperial clansmen) and Chinese, especially in North China, it has not yet been considered advisable to allow foreign doctors and their ambulance staffs to enter the field unless the Convention is accepted in its entirety, though there is no lack of volunteers among the Legation and missionary medical men. None of the missionary hospitals in the fighting area have been in any way touched by either side, and most of them are busy receiving sick and wounded soldiers.

Abuse of the Red Cross Flag.

At the Geneva Convention Great Britain and America did not agree with the other powers that the Red Cross symbol should be restricted solely to work carried out under the society's regulations. In Germany, for instance, it is a punishable offence for any firm to use the Red Cross as a trade mark. Examples of the regrettable misunderstanding as to the proper work of the society are occurring in Peking, where there is more than a tendency to use the Red Cross flag as a means to protect property and possessions which, if extended, will cause the flag to lose its power of protection. A benevolent society, with American missionaries at its head, has been started and has already sold several hundred Red Cross badges to the general public (Chinese) at a dollar each as a sort of insurance for the safety of their lives. The money thus raised has been honestly applied to the renting of quarters to which all wearers of badges could come for refuge, but no adequate protection would be available in the event of an outbreak, as the various guards would be confined to the defence of their respective legations. Though China is a signatory to the Convention the authorities do not intervene to ensure the legal and legitimate use of the symbol. There is much need of some authoritative representation of the society in China at the present moment to see that the Red Cross flag is only employed within the strict limits of the Geneva Treaty.

Plague in Siberia.

It is reported from Manchuria that bubonic plague has broken out at Sharasun, in Russian territory, about 35 miles from the Russo-Chinese frontier. There have been up to the present four deaths, and the Russian doctors have confirmed the nature of the epidemic. An understanding has been arrived at between the Russian and Chinese doctors regarding quarantine measures. The Russian doctors will have charge of the railway area and the Chinese doctors of the roads leading to it. The provisional quarantine station will soon be ready. It is not believed the condition is serious. The Prefect of Manchuria District and the Commissioners of Customs are acting in coöperation with the doctors.

Peking, Nov. 20th.

Obituary.

HENRY ROBERT HEATHER BIGG, F.R.C.S. EDIN., L.R.C.P. EDIN., A.I.C.E.

WE regret to announce that Mr. Henry Robert Heather Bigg died on Dec. 7th at his residence, Wimpole-street, London, at the age of 58, after a long and painful illness borne with great fortitude. Heather Bigg was educated at Rugby, Dr. Temple being then headmaster. When this distinguished man left Rugby, Bigg prepared the illumination for the address presented to him on that occasion. Heather Bigg loved outdoor sports and was captain of the football team, and kept his cap to the day of his death as one of the most cherished mementoes of his school days. He desired to be an artist, but at his father's wish he entered the medical profession and trained at University College Hospital; here he distinguished himself in comparative anatomy and zoology, as well as in practical physiology. He qualified in 1884 at Edinburgh. On the unexpected death of his father, Heather Bigg became engrossed in the practice of orthopraxy. Following in the footsteps of his father he devoted himself to the mechanical treatment of deformities, particularly interesting himself in the improvement of existing substitutes for lost limbs granted to soldiers. Though his professional life was devoted to this class of work, Heather Bigg's mental horizon was by no means limited by artificial limbs and spinal supports. He took a broad interest concerning education, and wrote an admirable tract on "A New View of National Education," and one on "The Human Republic." His love for the classical writers of antiquity did not end with his school days; to the last he delighted in the Latin authors, and Horace had for him an especial charm. In 1900 Heather Bigg published a story in blank verse, "Nell: A Tale of the Thames," containing delightful descriptions of rural scenes in the country near Oxford.

Heather Bigg had a wide circle of talented friends, with whom he loved to discuss questions relating to art and literature. He was very kind to his patients, took keen interest in their welfare, and was beloved in return. He was a zealous Freemason, and held high office in the craft. He was formerly surgeon to the Royal London Irish Volunteers, and the regimental flag was sent to serve as a pall at the funeral service. His body was cremated at Golder's Green. His friends of the Savage Club sent a beautiful wreath for the coffin on that occasion.

WALTER WYMAN, M.D.,

SURGEON-GENERAL OF THE UNITED STATES PUBLIC HEALTH AND MARINE HOSPITAL SERVICE.

Dr. Walter Wyman, supervising surgeon-general of the United States Public Health and Marine Hospital Service, died on Nov. 20th, as stated last week, in Washington, D.C. Dr. Wyman was born in St. Louis in 1848, and graduated in medicine at the St. Louis Medical College in 1873. In 1876 he entered the United States Marine Hospital Service, and after serving in St. Louis, Cincinnati, Baltimore, New York, and Washington, he was appointed in 1891 surgeon-general of the service. In the following year the service was expanded in scope, becoming the United States Public Health and Marine Hospital Service. Under Surgeon-General Wyman's administration many far-reaching and important improvements regarding the health of the United States—civil, naval, and military—were effected. He was instrumental in the establishment of sanatoriums for consumptive seamen. He was especially interested in problems concerning the health of those engaged in the merchant marine service. Dr. Wyman made a special study of the physical conditions under

which seamen were employed, and the result of his investigations is embodied in recommendations for legislation which have been passed by Congress. At his suggestion the first hospital for tuberculosis under Government auspices was established in New Mexico, and he also sought to have a hospital for lepers established in New Mexico, but the plan was abandoned in deference to local sentiment. He was instrumental in securing the enactment of laws relating to quarantine, and rendered the most valuable service in the prevention of cholera and yellow fever, in the Government regulation of the manufacture and sale of vaccine virus, antitoxin, and other therapeutic sera, and in the founding of the Hygienic Laboratory at Washington. He was chairman of the Committee on International Quarantine of the Pan-American Medical Congress in 1896 and of the Section of Public Health of the International Congress of Arts and Sciences at St. Louis in 1904; he was also president of the Section of State and Municipal Control of the International Congress of Tuberculosis in 1908. Dr. Wyman was a member of many societies, both national and foreign, and was an acknowledged authority on matters concerning public health, while the nature of his official services brought him into contact with the medical profession of all countries.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. J. H. Hollister, formerly professor of clinical medicine in the Northwestern University Medical School, Chicago.—Dr. J. F. W. Ross, professor of gynæcology in the University of Toronto.—Dr. H. A. Robbins, professor of dermatology in Howard University, Washington.

Medical News.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. E. Heyl has been appointed Medical Adviser to the Prussian Home Ministry, in succession to the late Dr. Aschenborn.—*Boston (Harvard University):* Dr. Howard T. Karsner, of Philadelphia, has been appointed Adjunct Professor of Experimental Pathology.—*Buenos Aires:* Dr. Pedro J. Pando has been appointed to the chair of Medical and Biological Chemistry.—*Heidelberg:* Dr. Menge, professor of midwifery, who was offered the chair at Bonn in succession to Dr. Fritsch, has declined to leave his present post.—*Iurieff (Dorpat):* Dr. Westernrik, of the Military Medical Academy, St. Petersburg, has been appointed to the chair of Pathology and Therapeutics.—*Kiel:* Dr. Heinrich Zoeppritz has been recognised as *privat-docent* of Surgery, and Dr. Heinrich Schlact as *privat-docent* of Medicine.—*Königsberg:* Dr. Hahn, of Munich, has been appointed to the chair of Hygiene.—*Lyons:* Dr. P. Courmont has been appointed to the chair of Experimental and Comparative Medicine, in succession to the late Dr. Arloing.—*Marburg:* Dr. Heyde has been recognised as *privat-docent* of Surgery.—*Moscow:* Dr. V. Muratoff, of Tomsk, has been appointed Extraordinary Professor of Neurology and Psychology.—*Naples:* Dr. Annibale De Giacomo has been appointed Extraordinary Professor of Traumatic Affections.—*Palermo:* Dr. Ugo Soli has been recognised as *privat-docent* of Pathological Anatomy.—*Philadelphia (University of Pennsylvania):* Dr. G. W. Norris has been appointed Adjunct Professor of Medicine.—*Pisa:* Dr. G. Volterrani has been recognised as *privat-docent* of External Pathology.—*Sienna:* Dr. G. Razzaboni has been recognised as *privat-docent* of External Pathology.—*Washington (Georgetown University Medical School):* Dr. Ralph A. Hamilton has been promoted to the chair of Histology.

INSTRUCTION IN HOSPITAL ADMINISTRATION FOR THE DIPLOMA OF PUBLIC HEALTH.—A three months' course of lectures and demonstrations in hospital administration will be given at the North-Western Hospital, Hampstead, N.W., and at the Grove Hospital, Tooting, S.W., during January, February, and March, 1912. In the case of each hospital the lectures and demonstrations will be identical, and students can attend on the day that best suits them. The fee for the course is £3 3*s*. At the North-Western Hospital the lecturer will be Dr. J. MacCombie, who will attend on Mondays at 3 P.M. and Thursdays at 11 A.M., beginning on Jan. 8th; and at the Grove Hospital Dr. J. E. Beggs will attend on Wednesdays at 3 P.M. and Saturdays at 11 A.M., beginning on Jan. 10th.

Dr. Legendre, who was reported as killed while on duty with a French scientific mission, is now stated to have been wounded only and to have arrived safely at Yunnanfu.

WEST OF ENGLAND CENTENARIANS.—Mrs. B. Gay, of Kingsdown, Bristol, celebrated the hundredth anniversary of her birthday on Dec. 1st.—Mrs. Sarah Bishop, who was born in March, 1810, died at Wareham, Dorset, on Dec. 5th.

THE After Care Association for Poor Persons Discharged Recovered from Asylums for the Insane appeals for funds to carry on and extend the work, the objects of which are to assist in various ways recovered cases on their discharge from asylums. Contributions should be sent to the secretary, Mr. H. Thornhill Roxby, Church House, Dean's Yard, Westminster, S.W.

DONATIONS AND BEQUESTS.—The late Mr. James Cook, of Weston-super-Mare. has bequeathed £1000 to the Dunster (Somerset) Cottage Hospital, and the residue of his property (after payment of specific legacies), which is estimated at about £36,000, will be divided equally between the Bridgwater Hospital, the Royal West of England Sanatorium, Weston-super-Mare, and the Taunton and Somerset Hospital.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL.—A Ladies' Association, of which Viscountess Portman is president, has recently been started to assist the hospital by obtaining subscriptions, gifts of ward linen, and so forth. The committee has made a strong appeal to ladies to join this new association, and contributions may be sent to the secretary at the hospital, Marylebone-road, N.W. Like all our charitable institutions, Queen Charlotte's Hospital is feeling the stress of the present disturbed financial conditions of the country; and although we cannot find space for the many Christmas appeals that reach us, we willingly call attention to this new auxiliary for the helping of a deserving charity.

PRESENTATIONS TO MEDICAL PRACTITIONERS.—On Dec. 1st, at Walter House, Bishop's Lydeard, the residence of Lieutenant-Colonel Dennis F. Boles, M.P., a 10 h.p. Darracq motor-car was presented to Mr. Emilien Edward Frossard, L.R.C.P. Lond., M.R.C.S. Eng. Mr. Frossard had a severe illness last spring, and several of his friends and patients thought that a car would be of great assistance to him in his professional work, and consequently subscribed for one for him.—At the Redland Park Mission, Bristol, Mr. William Ledingham Christie, M.D. New Zealand, F.R.C.S. Eng., was recently presented with a dressing-case by several friends and patients on the occasion of his leaving Clifton for Borneo.—At the annual distribution of certificates to members of the Bristol Great Western Railway Ambulance Class, Mr. John Thompson Wallace, M.B., B.Ch., B.A.O. Irel., was presented with a barometer, subscribed for by members of the class, in appreciation of his services as honorary lecturer.—The members of the Teignmouth (Devon) Section of the St. John Ambulance Brigade recently presented Mr. George Herbert Johnson, L.R.C.P.Edin., M.R.C.S. Eng., with a framed photograph of the members as a slight mark of appreciation of his services as honorary instructor.

THE SURGICAL AID SOCIETY.—The Lord Mayor of London presided at the annual meeting of this society, which was held at the Mansion House on Dec. 11th, when an eminently satisfactory report was presented and adopted on the proposal of Canon Simpson, seconded by Mr. Sheriff Briggs. The report showed that the total income amounted to £27,979 12*s*. 10*d*., as against £28,380 16*s*. 9*d*. in the preceding year. This apparent decrease was accounted for by the fact that legacies showed a decline of £2133. The real increase in the year's receipts, independently of legacies, was £1732 9*s*. 2*d*. Archdeacon Sinclair proposed, and Mr. Banks seconded, a vote of thanks to the governors of the society which was enthusiastically carried, as was also the re-election of Mr. Samuel Watson as treasurer. Mr. Watson, in his reply, pointed out that in 1869 when he first took

office the income of the society was £1050, while last year it reached £28,000, the number of patients relieved had increased from 692 to 26,000, and the number of appliances supplied to patients from 587 to 24,000. On the motion of Mr. Alderman and Sheriff Hanson, seconded by Mr. W. Wheatley, the committee was re-elected for the ensuing year, and the thanks of the governors to the honorary surgeons and other office bearers of the society were accorded to them on the proposition of the Rev. D. T. Young, seconded by Dr. H. G. Thompson. Mr. E. Muirhead Little having replied, the proceedings terminated with a vote of thanks to the Lord Mayor, who testified to the good work done by the society, and the great pleasure which it gave him and his sheriffs to lend a helping hand to so deserving a cause. During the course of the proceedings the secretary announced that nearly £450 had been collected in consequence of the meeting.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The National Insurance Bill and the Medical Profession.

IN the course of his speech on the debate on the third reading of the National Insurance Bill on Wednesday, Dec. 6th, the Chancellor of the Exchequer made a brief reference to the attitude of the medical profession. "On the question of the doctors," said Mr. LLOYD GEORGE, "I am treading on very delicate ground, strewn with suspicion. I am not going to say that the doctors are satisfied. After all, if they were to express satisfaction it would weaken what an honourable Member calls their trade union position. They have got to arrange with the Local Health Committee, and if they started by saying that they were satisfied of course it would be the greatest possible mistake that they could make. Still, what has been arranged at any rate in the Bill enables the process of free bargaining to go on between the Local Health Committees, the Friendly Societies, and the medical men. I defy anybody who undertakes this business to come to any other arrangements in an Act of Parliament. And why? Because the conditions vary in every locality. The system that suits Durham and South Wales is repugnant to Lancashire. There was danger of revolt among the doctors in the mining districts. We have given free choice of doctors. The system which suits part of Lancashire will not suit another part of that county. There is only one thing a Minister can do in any Bill dealing with the problem of national health, and that is to allow the Local Health Committee to arrange terms suitable to particular districts and suitable to particular individuals. If you were to keep it open, not for 12 months but for 12 years, you could not come to a better arrangement than that. Therefore, there is no real reason for postponement in that respect."

The National Insurance Bill in the House of Lords.

No obstacle it seems likely will impede the progress of the National Insurance Bill in the House of Lords. The attitude of the official opposition is to refrain from undertaking the amendment of the Bill and to leave to the Government full responsibility for its provisions. On the debate on the motion for the second reading of the Bill on Monday, Dec. 11th, the Marquis of LANSDOWNE reviewed the issues involved in the revision or rejection of the Bill by the House of Lords. He accepted the principle of National Insurance, but vigorously criticised many of the proposals of the Government's scheme. "We have," he said in conclusion, "to chose between the Bill, on the one hand, and, on the other, two or three years of bitter and disturbing controversy between the two Houses of Parliament which in the end would be absolutely fruitless. We have come to the conclusion that the acceptance of the Bill is the wiser course for this House to take. There is only one thing which we will not advise your lordships to do—a thing to which I should certainly decline to be a party. I mean a sham attempt to revise this Bill in the few remaining days of this session—an attempt which would be handicapped by the want of time at our disposal and by the knowledge that we are unable to touch or amend the greater part of the Bill. Such an attempt would be made with a certainty that we could not insist upon most of our amendments, and worse than that, we should be saddled with a share in the responsibility for the injustice and mischief which are written large upon many of the provisions of the Bill." After the leader of the Opposition had spoken those words it was evident that there would be no division on the second reading. Accordingly the Bill was read a second time without any vote being taken.

Viscount HALDANE, in moving the second reading of the Bill, made a long statement on its principles and purposes. With regard to the position of the medical profession, he had little to say. He made the brief statement that medical men would be dealt with by the Local Insurance Committees. He said that they would not be worse off than those who were now associated with the Friendly Societies, and on an average they would probably be 2*s*. better off than they now were in respect of each member of the societies.

In Lord LANSDOWNE'S speech reference was made both to voluntary hospitals and the medical profession under the Bill. He spoke of the alarm with which the former viewed the future, as their finances, now dependent to a large extent on the contributions of workmen and their employers, would suffer by the practical transference of this money to the Insurance Fund. As to the position of medical men under the Bill, he said that he scarcely ever opened his newspaper without seeing a fresh protest from them. He had always felt great sympathy for them. Medical men with working-class practices were about the hardest worked and least well remunerated amongst professional men. Some of the doctors certainly were still unsatisfied. Lord LANSDOWNE went on to say that the position of medical men under the Bill was not a very enviable one. They were at the mercy on the one hand of the Health Committees in which the insured persons would be a majority, and on the other hand at the mercy of the Insurance Commissioners who might strike medical men off the panel. He could not help thinking that if the Government desired the Bill to work successfully they would have taken pains to satisfy medical men on the points which they had raised. He wondered whether Lord Haldane had any knowledge of the movement for the establishment of a National Medical Union which he understood was to resist the effect of the Bill on the profession. A movement of this kind was not a negligible one, and he could not help thinking that the Government might have done more than they had to satisfy the apprehensions that had been felt.

Lord SANDHURST, in a speech which suffered a good deal from the acoustics of the House of Lords, also dealt with the position of the medical profession and hospitals. He expressed a doubt whether a flat rate of 6*s*. would constitute a proper remuneration for the services which the medical man would be called upon to give if he accepted the Act. He also thought that the demands on hospitals would increase, and that at a time when it was becoming more difficult to collect funds by voluntary donations. It seemed only too plain to him that now or in the near future the voluntary hospitals must take their place in the scheme. Lord SANDHURST pointed out that bound up with hospitals were the medical schools, and if they were shut down to any extent medical education would suffer greatly.

The Rag Flock Bill.

The Rag Flock Bill was read a third time in the House of Lords on Wednesday, Dec. 13th.

The University of Wales Bill.

The University of Wales (No. 2) Bill, which is designed to extend the provisions of the Medical Acts to the University of Wales and to graduates in medicine and surgery thereof, has been read a third time in the House of Lords.

HOUSE OF COMMONS.

WEDNESDAY, DEC. 6TH.

National Insurance Bill Topics.

Sir HILDRED CARLILE asked the Secretary to the Treasury whether, in view of the statement of the Chancellor of the Exchequer that the provisions for consultations and operations under the National Insurance Bill would be a matter for special arrangement, who were the parties to this special arrangement? and whether payments would be made under this head to the hospitals.—Mr. MCKINNON WOOD replied: The parties to the arrangement would ordinarily be the Local Insurance committee, the medical profession, and the patient. The answer to the last part of the question will depend upon the arrangements which are made.

Sir HILDRED CARLILE: Am I to understand that the hospitals will not be consulted in the matter?—Mr. MCKINNON WOOD: I said the medical profession. Of course, the medical profession represents the hospitals.

Sir HILDRED CARLILE: No. The honourable Member proceeded to ask the right honourable gentleman how the Chancellor of the Exchequer proposed to give effect to his intention that members of the medical profession who had shown themselves unfit for the performance of what would become a very responsible public duty must be prevented from securing work under the National Insurance Bill, and in what way doctors remaining on the Medical Register could be regarded as so unfitting themselves.—Mr. MCKINNON WOOD: The Insurance Commissioners will have power after due inquiry, in the exercise of their discretion, to remove from the panel the name of any medical man whose continuance thereon would be prejudicial to the efficiency of the medical service. The honourable Member can hardly expect me to enumerate the various possible causes that might lead the Commissioners to this conclusion, but I may point out that the Commissioners have power to delegate their duties of inquiry to referees appointed for the purposes, and such referees might be constituted as a court of medical inquiry.

Sir HILDRED CARLILE: Are we to understand that the medical men still on the Medical Register would be dealt with in this way and removed from the panels?—Mr. MCKINNON WOOD: A case might conceivably arise. I do not think it is very likely to arise, but in any case the medical committee would be able to express an opinion which would no doubt carry great weight with the Insurance Commissioners.

Sir HILDRED CARLILE: There is no medical committee.

Mr. MITCHELL-THOMSON: Have the doctors any right of appeal?

Mr. MCKINNON WOOD: Yes, to the referees.

Vaccination Officers.

Mr. PETO asked the President of the Local Government Board whether he was aware that the cases of vaccination officers on whose behalf he had intervened to get some compensation by gratuity or otherwise, to minimise their loss by the operation of the Vaccination Act and Order of 1907, were only those who had appealed to the Local Government Board past the guardians, and, seeing that these cases were

consequently only a small fraction of the cases in which loss and hardship had been suffered, and that many of the officers had thought it wiser to suffer loss rather than run the risk of antagonising their employers, whether he would state what action he proposed to take.—Mr. BURNS answered: I have had this subject before me for some time, but I do not at present consider that I should intervene unless I am appealed to. An officer with a genuine grievance need not, in my opinion, be deterred by the consideration suggested from making such an appeal.

The Royal Commission on Tuberculosis.

Mr. CHARLES BATHURST asked the President of the Local Government Board whether, in view of the admission by the Royal Commission on Human and Animal Tuberculosis in their final report that man's liability to infection from tuberculous animals remained a matter only of inference, he would consider the desirability of pursuing further investigations with the object of discovering whether the residence of human tubercle bacilli in the bodies of infant children or adults led to such modification as to render them indistinguishable from bovine tubercle bacilli.—Mr. BURNS replied: In regard to the first part of the question I would draw attention to the statement on p. 35 of the Final Report that the Commission has investigated many instances of fatal tuberculosis in the human subject in which the disease was undoubtedly caused by a bacillus of the bovine type and by nothing else. The conclusion of the Commission is that man must be added to the list of animals notably susceptible to bovine tubercle bacilli. I am not at present prepared to make any statement in regard to future investigations of the subject referred to in the second part of the question, but may I refer the honourable Member to the observations of the Commission on this point which appear on pages 35 to 37 of their final report.

Mr. BATHURST: Are all investigations into this disease at an end so far as the department of the right honourable gentleman is concerned.—Mr. BURNS: Before I answer that question I would suggest to the honourable Member that he should read the final report completely with the last memorandum.

Mr. BATHURST asked the right honourable gentleman whether the statistical information relating to abdominal tuberculosis, stated at page 49 of the Second Interim Report of the Royal Commission on Human and Animal Tuberculosis to have been received from the great hospitals and about to be published in a subsequent Report, had yet been so published; and, if so, what was the reference.—Mr. BURNS answered: A further reference to these records is contained on page 49 of the memorandum attached to the Final Report of the Commission, from which it will be seen that subsequent examination of the records showed that they were of little value for the purposes of the Commission.

Mr. BATHURST asked the right honourable gentleman whether any information had been published either by the Board or by any Royal Commission or Departmental Committee on Tuberculosis as to the efficacy of the process of the pasteurisation of milk in the destruction of tuberculous germs and as to the effect of such process upon its nutritive value; and if not, whether he proposed to institute such investigation.—Mr. BURNS said in reply: Information on this subject is contained in paragraphs 70 to 76 of the report of the Royal Commission on Tuberculosis of April 3rd, 1895. Since that time numerous other observations have been made by other workers, the results of which have been published in various journals. As to the latter part of the question, a report will shortly be published by the Local Government Board.

Mr. BATHURST: Will the results of these different investigations be assembled in one document?—Mr. BURNS: I think that sufficient reference will be made to them by the report which is now in process of preparation by the Local Government Board.

The Health of Postwick.

Sir ROBERT PRICE asked the President of the Local Government Board whether his attention had been drawn to the danger to health which was caused to the inhabitants of Postwick, near Norwich, by the deposit by the Corporation of Norwich of both sewage and dry refuse, and whether the department could do anything to improve this state of affairs.—Mr. BURNS wrote in reply: I have given close attention to this matter and have twice directed a visit by an inspector of the Board to inquire into it. The corporation are now taking steps to remove any cause of nuisance from their sewage farm, and they have improved the conditions under which the refuse is deposited.

Insurance Commissioners for Ireland.

On the motion for the adjournment, Mr. MOONEY asked the Home Secretary whether he was in a position to give information with regard to the Commissioners for Ireland under the National Insurance Bill.—Mr. MCKENNA: The names are: Mr. Joseph A. Glynn, chairman of the Galway County Council, who will be chairman of the Commission, Mr. Walter Kinnear, of Dublin, Dr. Walter Joseph Maguire, of Belfast, and Mrs. Dickie, of the Local Government Board, Dublin, will be the other Commissioners. The secretary will be Mr. J. Houlihan, an experienced member of the upper division of the civil service.

THURSDAY, DEC. 7TH.

The National Insurance Bill and Medical Practices.

Mr. DOUGLAS HALL asked the Chancellor of the Exchequer whether the Government proposed to take any steps to compensate doctors for the loss many of them would suffer in the price obtainable for the sale of their practices owing to the working of the National Insurance Bill when it came into operation.—Mr. LLOYD GEORGE said in reply: I see no reason to suppose that the consequences anticipated by the honourable Member are likely to occur. On the contrary, the value of most medical practices, especially in industrial areas, must be increased by the operation of the Bill.

TUESDAY, DEC. 12TH.

National Insurance Bill Topics.

Viscount WOLMER asked the Prime Minister whether he intended to appoint a Parliamentary Insurance Minister, and if not, who would be responsible to Parliament for the Administration of the Government's insurance scheme.—Mr. ASQUITH replied: The Treasury will be responsible for Part I. (National Health Insurance) of the insurance scheme. It may be convenient that I should state that the joint Committee to be set up under Clause 83 of the Bill will consist of a chairman, the four chairmen of the Commissions, Mr. Bradbury, Mr. Smith Whitaker, and the Chief Registrar of Friendly Societies. The present Under Secretary for the Home Office will be chairman, and will reply in this House in respect of the work of the joint Committee and of the four Commissions, and Sir Robert Morant will be vice-chairman.

Mr. CROFT asked the Chancellor of the Exchequer whether qualified compounders and dispensers of medicines of the Royal Army Medical Corps, having businesses of their own, would be allowed to submit their names as eligible to dispense prescriptions under the National Insurance Bill.—Mr. LLOYD GEORGE answered: Compounders and dispensers of medicine who are qualified under the rules of the Pharmaceutical Society and who have left the Royal Army Medical Corps are eligible to be placed on the list of dispensers under the National Insurance Bill.

Mr. BAIRD asked the right honourable gentleman whether a medical practitioner would be allowed under the National Insurance Bill to have his name included among the list of practitioners in more than one area administered by more than one Local Health Committee.—Mr. LLOYD GEORGE replied: The answer is in the affirmative.

BOOKS, ETC., RECEIVED.

BALE (JOHN), SONS, AND DANIELSSON, LIMITED, London. KABITZSCH, CURT, Wurzburg.

The Accessory Sinuses of the Nose in Children. 102 Specimens reproduced in natural size from Photographs. By Prof. Dr. A. Onodi, Director of the University Clinic for Diseases of the Nose and Throat in Budapest. With a Preface by Prof. Dr. W. Waldeyer, Director of the Anatomical Institute of the University of Berlin. Translated by Carl Prausnitz, M.D., M.R.C.S., L.R.C.P., Head of the Hydrophobia Department of the Hygienic Institute, University of Breslau; late Assistant Bacteriologist to the Metropolitan Asylums Board, London. Price 21*s.* net.

Atlas of Killian's Tracheo-Bronchoscopy. Coloured Plates representing Pathological Preparations from Cases examined during Life by means of Tracheo-Bronchoscopy. THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Diss, in the county of Norfolk; and at Stromness, in the county of Orkney.

Births, Marriages, and Deaths.

BIRTHS.

COTES-PREEDY.—On Dec. 9th, at Harboro' Cottage, Gerrard's Cross, the wife of Digby Cotes-Preedy, M.A., LL.M., L.S.A., Barrister-at-Law, of a son.

MARRIAGES.

CRUDDAS—LUNHAM.—On Dec. 7th, at Trinity Presbyterian Church, Cork, Major Hamilton Maxwell Cruddas, I.M.S., Queen's Own Corps of Guides, Mardan, India, to Helen Madoline, youngest daughter of the late Thomas Lunham, J.P., and Mrs. Lunham, Lotamore, Cork.

SMYTH—RUBIE.—On Dec. 7th, at Bromley, Kent, Ernest Jackson Smyth, M.D., B.S., B.Sc. Lond., to Marion Janet, second daughter of Edward Rubie, Sidcup, Kent.

DEATHS.

BOND.—On Dec. 5th, at Beaufort-buildings, Gloucester, Francis Thomas Bond, B.A., M.D. Lond., F.R.S. Edin., aged 77 years.

MAPLETON.—On Dec. 10th, at Goudhurst, George Hubert Mapleton, M.B., C.M. Edin., after a short illness.

TREVELYAN.—On Dec. 11th, Edmond Fauriel Trevelyan, M.D., of Park-square, Leeds, aged 52 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

IMPRISONMENT FOR OVERLYING.

PUBLIC opinion has been considerably stimulated during the past few years on the question of infantile mortality, and it is believed that many of the provisions of the Children Act will be found in the course of time to have been the means of bringing about a considerable reduction in the number of deaths of infants. Within the past few months the Brighton coroner has had before him numerous cases of overlying, and on every occasion Mr. J. E. Bush has taken the opportunity of calling attention to the very dangerous practice of parents taking their offspring to bed with them instead of placing them in a cradle or making a bed in a drawer of a chest of drawers or a crude box; in fact, anything rather than the common practice of the child sleeping with the parents. Considerable prominence has been given to the coroner's utterances in the lay press, but apparently with little effect, for in Brighton during October there were no fewer than three cases of overlying. The month of November opened badly with another instance, but as both the mother and the father are now undergoing a term of imprisonment there should be, and perhaps will be, an appreciable absence of these cases in the Brighton coroner's court. There were certainly some very aggravated circumstances in the latter case. A railway employee and his wife had spent the evening together drinking and both went home, the husband "absolutely drunk and the wife not so drunk but under the influence of drink," according to the evidence. The man engaged in a street brawl with a male lodger, inflicting such injuries upon that individual as to necessitate hospital treatment. The husband and wife then went to bed, taking their month-old child with them, and in the morning the child was dead. A medical man found that the thymus gland was five times its normal size. Acting on the advice of a nurse the mother had purchased a cradle for the child, but pending the preparation of the bedding the cradle was only the bed of a cat. It is scarcely necessary to add that bearing in mind the condition of the parents the jury found there was negligence, but which did not amount to culpable negligence, and in returning a verdict of "Death from suffocation" the jury was agreed that the parents had rendered themselves liable under a section of the Children Act to summary conviction before the magistrates. The opinion was further expressed that it was time severe steps were taken in the matter. The National Society for the Prevention of Cruelty to Children at once instituted proceedings in the police-court, and on Nov. 16th both father and mother were sent to gaol for two months, the justices telling them that they were lucky in not being proceeded against on a charge of manslaughter. It was the first prosecution of the kind in Brighton, and it will be interesting to note what effect the sentence has upon parents who will not take heed of the frequent warnings that are given to them.

FEDERATED MALAY STATES: MEDICAL REPORT.

THE Federated Malay States are situated on the mainland of the Malay Peninsula, and are closely connected with the Straits Settlements; they consist of the States of Perak, Selangor, Negri Sembilan, and Pahang, which by treaty in 1895 renewed their engagements with the British Government and are administered under the advice of a British Resident-General, who controls the Residents subject to the instructions of the High Commissioner, who is also Governor of the Straits Settlements. The first three States named are on the west coast and extend from the border of Province Wellesley to that of the independent State of Johore. Pahang is on the east coast. All are governed by their native rulers under the above-mentioned control. Kuala Lumpur, the capital (population 40,000), is distant 8500 miles from London (transit, *vid* Penang, 21 days). The official report for 1910 has just been presented to Parliament. Subjoined is a summary of the medical section of the report. The death-rate, on the estimated population of the States—1,001,257—was 32·16 per 1000. The number of in-patients treated in hospitals was 89,824, as against 73,192 in 1909 and 84,105 in 1908. The death-rate there was 8·15 per cent., the lowest recorded. Of the 6192 deaths, 1092 were due to malaria, 1234 to dysentery, and 1357 to pulmonary diseases. The record number of 217,407 out-patients were treated during the year. The travelling dispensaries, which include dispensary boats on the Perak and Pahang rivers, supplied aid to the large riverside population and to places where no regular dispensaries are established. Anti-malarial measures have engaged attention. Some $21,000 were expended during the year on drainage and reclamation of swampy land at Kuala Lumpur; similar works have also been executed in Klang, Port Swettenham, Batu Gajah, Seremban, and elsewhere. Large quantities of quinine were also distributed. During the year 1909 there were no cases of cholera or plague, but unfortunately during 1910 cholera broke out in Perak, Selangor, and Pahang. It is believed that the outbreak at Pahang was introduced from Siam and that in the other two States from India. There were 378 cases and 332 deaths. 225 cases of small-pox were recorded, 60 of which were fatal. During the year 1909 33,782 persons were vaccinated; during 1910 the number rose to 121,568. The number of known successful vaccinations was 80,617, and of unsuccessful 8561; the remainder were not verified. At the Institute for Medical Research the investigation into the etiology of beri-beri was proceeded with. An inquiry on the distribution of anophelines was commenced and will be continued for the purpose of obtaining further data regarding the malaria-carrying mosquito. 246 reports were furnished on the examinations of specimens submitted by the medical and veterinary departments. In addition to 764 general analyses, a number were carried out in the research on beri-beri. 136 analyses were made under the Deleterious Drugs Enactment, and 94 of these were samples of anti-opium pills; the analyses proved that 89 of these samples contained a large proportion of opium or morphine.

HANDBOOKS ON DISINFECTION.

Messrs. Newton, Chambers, and Co., Limited (Thorncliffe, near Sheffield), ask us to state that they will gladly send their series of handbooks on disinfection to readers of this journal on receipt of a post-card. "Medical Izal" contains reprints from the principal medical journals of papers dealing with the use of izal in the treatment of phthisis, puerperal sepsis, tropical dysentery, enteric fever, cholera, and tinea favosa capitis. "Practical Disinfection" deals with the domestic uses of izal. "The Veterinary Handbook" is full of useful information for owners of horses, dogs, cats, poultry, &c. The last of the series, "Izal in the Dairy," apart from its purpose as an advertisement, is a really useful handbook at a time when the conditions of milk production are claiming so much attention.

SOUTH AMERICAN PARASITES.

A VALUABLE collection of parasites infesting human subjects and domestic animals in Dutch Guiana and a number of preparations illustrating them have been presented to the University of Utrecht through Dr. E. A. Koch, of the Dutch Colonial Medical Service in Paramaribo.

THE DOMEN ADHESIVE ELASTIC BANDAGE.

WHEN noticing this excellent make of elastic bandage we mentioned, owing to a misunderstanding of the description, that it contained no lead; we find that this is an error, but it does not affect the value of the plaster for the purposes for which it is intended. It is certainly a very useful and convenient form of strapping.

Rapier.—Our correspondent should advise any of his patients against having recourse to the treatment. The whole matter is still under our consideration, but we have already enough evidence to justify this warning.

Si Opus Sit.—Our correspondent's idea is ingenious and the coincidence is humorous.

"*Not to be Swallowed*" has failed to give his name and address.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

THE following Congresses, Conferences, and Exhibitions are announced for 1911:—

Dec. 19th-23rd (Moscow).—Third Pan-Russian Therapeutical Congress.
,, 27th-30th (Baltimore).—American Physiological Society.

In 1912:—

Jan. 20th-27th (Hong-Kong).—Second Biennial Congress of the Far Eastern Association of Tropical Medicine.
Feb. 13th-14th (London).—Central Poor-Law Conference.
March 7th-11th (Berlin).—Thirty-third Balneological Congress.
,, 23rd-April 4th (London, Royal Agricultural Hall).—International Smoke Abatement Exhibition.
,, (London).—First Congress of Pure Food and Health Society of Great Britain.
April 1st-7th (Tunis).—Twenty-second Congress of French-speaking Alienists and Neurologists.
,, 14th-20th (Rome).—Seventh International Congress on Tuberculosis.
,, 15th-18th (Wiesbaden).—Twenty-ninth German Congress for Internal Medicine.
,, (Rome).—Seventh International Congress of Dermatology and Syphilology.
,, (Giessen).—Congress on Study of Families, Inheritance, and Race Hygiene.
Spring (London).—Second Optical Convention.
May 7th-17th (Washington).—Ninth International Red Cross Conference.
,, 27th-June 1st (London).—Eighteenth International Congress of Americanists.

May (London).—International Horticultural Exhibition.
June 24th-27th (London).—The (Biennial) Health Conference and Exhibition.
,, (London).—Missionary Exhibition.
,, (Dublin).—Celebration of the Bicentenary of the School of Physic in Ireland (Medical School of Trinity College, Dublin).
July 2nd-5th (London).—Congress of the Universities of the Empire.
,, 2nd-6th (Doncaster).—Seventy-third Annual Show of the Royal Agricultural Society of England.
,, 12th-16th (London).—Imperial Conference of Teachers' Associations.
,, 19th-27th (Liverpool).—British Medical Association, Eightieth Annual Meeting.
,, 24th-30th (University of London).—First International Eugenic Congress.
,, 25th-28th (Berlin).—Royal Institute of Public Health.
,, 29th-August 3rd (York).—Congress and Exhibition of the Royal Sanitary Institute.
Aug. 5th-10th (Oxford).—Second International Congress of Entomology.
,, 7th-10th (Glasgow University).—Thirty-second Annual Meeting of the British Dental Association.
Sept. 4th (Washington, D.C.) and Sept. 6th-13th (New York).—Eighth International Congress of Applied Chemistry.
,, 10th-12th (Berlin).—Sixth International Congress of Obstetrics and Gynæcology.
,, 23rd-28th (Washington, D.C.).—Fifteenth International Congress on Hygiene and Demography.
September (Prague).—International Congress of Radiology and Medical Electrology.
(Budapest).—Tuberculosis Exhibition.
(Stockholm).—Olympic Games.
(Düsseldorf).—Third International Medical Accident Congress.
(Perth, Western Australia).—(Three days.) Health Congress.

In 1913:—
(Easter week) (Berlin).—Fourth International Congress for Physiotherapy.
Aug. 6th-12th.—(London).—Seventeenth International Congress of Medicine.
,, 22nd-28th (Cambridge).—International Mathematical Congress.
(London).—Historical Medical Exhibition. (Organised by Mr. Henry S. Wellcome.)
(Chicago).—Congress of the International Association of Refrigeration.
(Paris).—Congress of Physical Education.
(Milan).—Fourteenth International Anti-alcoholic Congress.

In 1914:—
(Vienna).—Third International Congress for Professional Diseases.
(Auckland, N.Z.).—Australasian Medical Congress.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL METEOROLOGICAL SOCIETY, Institute of Civil Engineers, Great George-street, Westminster, S.W.

WEDNESDAY.—7.30 P.M., Mr. W. Larden: Solar Halos and Brocken Spectres.—Mr. W. H. Dines: The Statistical Changes of Pressure and Temperature in a Column of Air that accompany Changes of Pressure at the Bottom.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. Dr. Simson: Diseases of Women. 12 noon: Dr. Bernstein:—Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Dr. Pritchard: Clinical Pathology.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 11.30 A.M.: Mr. Etherington-Smith: Demonstration of Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Mr. Etherington-Smith: Clinical. (Lecture II.)

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.), Hospital operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

K.—Dr. G. Kirkwood, Peterborough.

L.—Rev. W. A. Liston, Govan; Dr. T. Laird, Manchester; Mr. C. Lupton, Leeds; Mr. T. S. Logan, Exminster; Mr. W. E. Lee, Lond.; Dr. A. P. Luff, Lond.; Dr. L. R. Lempriere, Hertford; Mr. A. E. G. Langschmidt, Worcester, S.A.; Dr. A. H. N. Lewers, Lond.; Dr. A. Leggatt, Lond.; Major J. C. Holdich Leicester, I.M.S., Lond.

M.—Dr. G. R. Murray, Bowdon; Mr. A. S. Morley, Lond.; Messrs. Menzies and Co., Edinburgh; Medical Times Publishing Co., Lond.; Lieutenant-Colonel T. R. Macdonald, I.M.S., Inverness; Mr. J. E. R. McDonagh, Lond.; Dr. W. A. Mott, Rathwell, Canada; Messrs. Marston, Thompson, and Evershed, Burton-on-Trent; Dr. W. H. Millar, Lond.; Sir H. Morris, Bart., Lond.; Dr. E. C. Morland, Arosa; Mr. J. Milner-Adams, Lond.; Dr. G. D. McRae, Ayr; Messrs. Murphy and Lonsdale, Leeds; Mr. J. J. McGrath, Limerick; Mr. E. Merck, Lond.; Major R. H. Maddox, I.M.S., Alipore; Mr. H. Jan Mahomed, Bombay; Mr. E. Mahony, Liverpool; Dr. J. C. Muir, Lond.

N.—Dr. H. P. Noble, Lond.; Mr. W. Noble, Wimbledon; Messrs. Naylor, Benzon, and Co., Lond.; Mr. F. L. Nicholls, Fulbourn.

O.—Messrs. Osborne-Peacock Co., Manchester; Dr. Cyril Ogle, Lond.

P.—Mr. P. Phillips, Florence; Mr. C. H. Powers, West End; Mr. J. E. Purvis, Cambridge; Mr. H. I. Pinches, Lond.; Mr. J. Phillips, Lond.; Miss C. E. Pring, Nida-Davoli, India; Mr. S. K. Pal, Darjeeling, India; Mr. S. Paterson, Farnborough; Dr. R. W. Philip, Edinburgh; Mr. S. Phillips, Lond.; Messrs. Parker and Sons, Oxford; Dr. A. E. Porter, Reigate.

Q.—Queen Margaret College, Glasgow.

R.—Mrs. Rich, Bournemouth; Mr. R. P. Rowlands, Lond.; Royal Hospital for Incurables, Dublin, Secretary of; Messrs. E. and J. Richardson, Newcastle-on-Tyne; Mr. C. Ryall, Lond.; Dr. A. Reid, Blackburn; Messrs. Reitmeyer and Co., Lond.; Dr. G. Rankin, Lond.; Royal Alexandra Infirmary, Paisley, Clerk to the; Messrs. Raimes and Co., York; Mr. A. K. T. Raw, Kampli, India; Mr. A. Russell, Lond.; Mr. L. B. Rawling, Lond.; Mr. J. K. Reeve, Lond.

S.—Mr. H. Batty Shaw, Lond.; Dr. J. Stewart, Lond.; Messrs. Swets and Zietlinger, Amsterdam; Messrs. Spiers and Pond, Lond.; S. S. M. W.; Mrs. Salmon, Glasgow; Dr. F. J. Smith, Lond.; Shropshire County Asylum, Shrewsbury, Clerk to the; Mr. S. Sharpe, Lond.; Mr. J. B. Shattock, Lancaster; Mr. R. H. J. Swan, Lond.; Dr. C. A. Shaw, Bedford; Miss F. A. Stoney, Lond.; Dr. R. Saundby, Birmingham; Dr. T. Shennan, Edinburgh; Mr. E. Simpson, Epperstone; Seamen's Hospital Society, Lond., Secretary of; Dr. S. J. Sharkey, Lond.; Messrs. W. H. Smith and Son, Birmingham; Dr. P. W. Schmidt, York; Dr. Lewis A. Smith, Lond.; Dr. W. Woodcliff Smith, Lond.; Messrs. Scott and Bowne, Lond.; St. Mungo's College, Glasgow, Secretary of; S. G. M.; Southampton Free Eye Hospital, Secretary of; Dr. G. H. Sievekking, Hamburg.

T.—Mr. E. D. Telford, Manchester; Dr. J. L. Timmins, Lond.; Tunbridge Wells General Hospital, Secretary of.

U.—University College, Dublin, Secretary of.

V.—Mrs. Veitch, Edinburgh; Dr. R. Vincent, Lond.

W.—Dr. G. T. Western, Lond.; Mr. J. R. Woodcock, Sawrey; Dr. A. F. Wilson, Lond.; Dr. J. Sims Wallace, Kingston-on-Thames; Dr. J. F. Ward, Stockport; Dr. R. M. Williams, Lond.; Mr. G. Westby, Liverpool; Dr. R. Waterhouse, Bath; Messrs. F. Williams and Co., Lond.; Mr. J. B. Wall, Lond.; Mr. R. W. Waring, Cavendish; Mr. A. J. Walton, Lond.; Dr. H. B. Weir, Lond.; Mr. R. E. H. Woodforde, Ashwell; Mr. Sinclair White, Sheffield; Dr. F. Parkes Weber, Lond.; Mr. J. W. T. Walker, Lond.; Dr. R. C. B. Wall, Lond.; Dr. J. W. White, Glasgow; Wigan Infirmary, Secretary of; Mr. H. E. Worthington, Birchington; W. D. D.; W. S.; Dr. Wotherspoon, Lond.; Dr. Prosser White, Wigan.

Y.—Dr. E. Young, Lond.

Z.—Messrs. A. and M. Zimmermann, Lond.

The Bradshaw Lecture

ON

SOME POINTS IN HEREDITY.

Delivered at the Royal College of Surgeons of England on Dec. 6th, 1911,

BY R. CLEMENT LUCAS, B.S., M.B. LOND., F.R.C.S. ENG.,

CONSULTING SURGEON TO GUY'S HOSPITAL, AND TO THE EVELINA HOSPITAL FOR SICK CHILDREN.

MR. PRESIDENT AND GENTLEMEN,—There is, perhaps, nothing more remarkable, in comparing the teaching of former years with that of the present day, than to note the gradual recession and disuse of the word *diathesis*, as the true microbic cause of diease after disease becomes unravelled.

CRITICISM OF DIATHESIS.

This word was used to indicate a constitutional condition derived from the parents, rendering a person liable to a particular disease—a disease developed from the tissues conveyed to him by his parentage. Lecturers spent many hours in elaborating details of such diatheses as the strumous, cancerous, syphilitic, gouty, rheumatic, nervous, plethoric, lymphatic, and so on. But after a time it became evident that the types described as characteristic were those in which a particular disease or habit had already commenced its work. And now they have passed away like a dream, from which the slumberer awakes to enter into new realms of thought. Yet great was their influence, and mighty were the struggles made by observers to force their irregular cases under the unsympathetic wings of some particular diathesis.

The Gouty Diathesis.

Of these, the gouty is almost the last survivor, bolstered up by its aristocratic relations, and even more by the parvenu's wealth, waiting, as I believe, only for the discovery of a particular ferment which causes the precipitation of sodium urate in the most used joint of an overfed, often sedentary, and perhaps bibulous person.

In this relation it may be interesting to quote Professor Laycock's account of the diathesis of the revered founder of this great museum. The Professor of Medicine of Edinburgh thus describes his brother Scot:—

> John Hunter was of the strumous arthritic diathesis with a nervous element also. [A little mixed, you will observe.] His florid complexion indicated the vascular element, while his rounded forehead, thickened alæ nasi, thick upper lip, and caries teeth in the upper jaw marked the strumous tendency.

He then proceeds to account for these hereditary defects:—

> John Hunter, it is clear, owed his strumous arthritic diathesis to the circumstance that his father was in his seventieth year when John was conceived and had at least one of the diseases of the gouty habit, namely, "gravel."

He sums up:—

> He was a typical man of his diathesis; with a predisposition to tuberculosis and atheroma, he nevertheless, from the vigorous nutrition of his nervous system, was capable of great mental labour.[1]

Such is the libellous description given of the greatest surgeon of his day.[2]

Tuberculosis.

Of diseases believed to be hereditary, the constitutional origin of none was taught with more dogmatic certainty than tuberculosis before the discovery of Koch's bacillus; and even now, though the various modes of entry and the manner of its distribution have long been studied, it is difficult to disentangle men's thoughts from this erroneous teaching. So deeply was this view of its constitutional origin instilled in the minds of the profession that acute observers shut their eyes to the most obvious cases of infection; yet there must have been some sceptics even in those days of darkness, for I find Sir Samuel Wilks writing in the *Guy's Hospital Reports* for 1869 as follows:—[3]

> It does appear most remarkable that whilst many of us have been speaking in the most positive terms of the inherited causes of consumption, there have been those who have no hesitation in looking upon it as a disease like small-pox, accidently introduced from without.

These believers in an outside cause were at that time in a hopeless minority. The great text-book authority, Sir Thomas Watson, thundered out his opinion as follows:—

> Is phthisis contagious? No, I verily believe it is not. A diathesis is not communicable from person to person; nor is the disease ever imparted to another, even by one scrofulous individual to another.

He then proceeds to explain away a most obvious instance of infection:—

> A wife watches the death-bed of her consumptive husband, and presently sinks herself under consumption; and there may be no tubercle or acknowledged examples of scrofula in her pedigree. Yet even here the latent diathesis may fairly be presumed to have existed. Very few families are perfectly free from strumous inter-mixture.

Could the blinding effect of a predominant theory be more clearly exposed than by this explanation?

There is no such thing as hereditary tuberculosis. Infants are not born tuberculous any more than the children of leprous parents are born leprous. We are dealing with a disease both infectious and inoculable, the bacillus of which has been known for 30 years. During that period better hygiene, housing, and food have reduced the mortality due to tuberculosis from 25 to 10 in every 1000. By complete segregation the disease could be as certainly stamped out as hydrophobia was by the courageous muzzling order of Mr. Walter Long, to whom all honour is due. Of what service is it to inquire whether one family is more liable than another to this disease when all are liable, and 97 per cent. of 500 consecutive necropsies were found by Naegeli to show evidence that tuberculous infection had at one time taken place? Statistics to prove an hereditary predisposition are useless, unless taken of persons removed immediately after birth from the tubercle-infected house, and from contact with relatives already infected.

Syphilis.

Another diathesis we were taught was the syphilitic, but we know now that there is no such thing as hereditary syphilis. This is an inoculable disease, the organism causing which was discovered by Schaudinn in 1905, and it may be *transmitted* through the mother to her child when the placental protection breaks down, but there is no reliable evidence of its ever having been carried on to a third generation. It is a disease distributed by folly and reaped by innocence, and those well-meaning people who discovered in this disease a divine scourge to be carried on to the third and fourth generations must be disappointed by its limits. The moment the spirochæta pallida was demonstrated it became evident that as the greater could not be carried by the less, direct transmission from the male to the ovum was out of court. The mother must first be infected, though the disease may not have been noticed, and Colles's law, which states that a mother cannot be inoculated on the nipple by her syphilitic infant, receives additional support by this discovery. It also emphasises the importance of directing attention especially to the treatment of the mother in order that the children may be born free from the disease.

Leprosy.

Of diseases assumed to be hereditary, none has carried this reputation through a longer period than leprosy, which was regarded as hereditary as far back as Biblical times; and this belief will be kept in remembrance by Elisha's curse on his servant Gehazi: "The leprosy therefore of Naaman shall cleave unto thee, and unto thy seed for ever." Its contagiousness was also recognised from the earliest times, so that lepers became outcasts, and segregation has for centuries been the means employed to prevent the spread of the disease. Hansen discovered the bacillus lepræ in 1871. An Indian Commission failed to trace histories of the disease in the families of more than 5 or 6 per cent.; children born of leprous parents are not leprous, and if removed from their parents seldom become so. This, again, is a disease which has been placed among ordinary contagious diseases as the result of modern discoveries, and the belief in its hereditary

[1] Medical Times and Gazette, vol. i., 1862.

[2] The arthritic diathesis has been deprived of acute rheumatism by the discovery of the diplococcus rheumaticus, and if Mr. Goadby's observations prove correct as to a bacillus connected with tooth-sockets (published in THE LANCET of March 11th, 1911) being the cause of osteo-arthritis, the diathesis will be still further depleted.

[3] On the Nature and Causes of Disease, Guy's Hospital Reports, 1869, p. 19.

transmission which held sway for tens of centuries has been scattered to the winds.

Malaria.

Not many years ago malaria was described as a climatic diathesis, by which it was intended to imply that a constitutional condition was brought about by residence in certain climates, and that it became hereditary. The protozoon of malaria was discovered by Laveran in 1880, and its life-history and mode of inoculation have since been so clearly demonstrated that any idea of its being associated with a diathesis would strike everyone now as being utterly absurd.

Cancer.

The diathesis of cancer was never asserted with the same absolute confidence as was that of tuberculosis, and the profession has been about equally divided as to whether it was an hereditary disease or not. Sir James Paget taught that it was a blood disease which caused local manifestations, but the evidence of its commencement as a local disease is now overwhelming. John Birkett, at one time a great authority, going over his cases found cancer more common in families without history of cancer than in those families in which there was a history of the disease, and Paget could only trace a family history in one in three of his private patients, and in one in five or six among hospital patients; whilst Harrison Cripps, 33 years ago, showed that if the evidence of heredity derived from collaterals and doubtful cases were excluded there remained only a number similar to that expressing the normal frequency of cancer to the whole population. Dr. Bashford states that among persons over the age of 35 the chance that a man will die from cancer is one in eleven, and of a woman above the same age one in eight; and so great is the frequency of cancer as a cause of death above that age that in one of every two families a parent or a grandparent will, on an average, have died from cancer. The influence of heredity in man must therefore be regarded as insignificant. It is true that by careful selection and in-breeding Dr. Bashford has produced a race of mice more liable to spontaneous cancer than those of a sound stock, but he warns us that experiment shows that those of cancerous stock are not more liable to implanted cancer than others.

To my mind we arrived half-way to the discovery of the cause of cancer when it was shown that the disease was inoculable in animals of the same species. We are dealing with *a mildly contagious disease slowed down by age.* This conceded, many observations fall readily into line. Thus, Sir Henry Butlin's cases, indicating that the instances on which heredity was based were all on either the father's or on the mother's side, would admit of the explanation that these individuals were more intimately associated and so more liable to contagion. It explains the occurrence of several instances in the same house. It explains also the death of husband and wife from the same disease, of which I will mention three instances. A lady was operated on for cancer of the uterus, subsequently her husband died from cancer of the liver, and later she died from recurrence of the original disease. A gentleman I frequently meet in the City is one of six sons, all living and healthy, whose ages range between 53 and 70. His father died at 57 from cancer of the rectum and his mother at 61 from cancer of the breast. He had one sister who lived with her parents and attended them in their last illnesses. She died from cancer of the breast, and what makes the probability of contagion stronger is the fact that the nurse also developed cancer and died from it. I operated on a lady in 1898 with so extensive a recurrence of cancer in the axilla that I removed both axillary artery and vein in dissecting out the growth. The wound healed primarily and she had no after recurrence, but five years later she died from acute ptomaine poisoning from eating potted meat at a ball supper. A post-mortem examination showed no evidence of cancer anywhere, but there was extensive ulcerative colitis. Her husband subsequently died from cancer of the rectum.

The tendency of modern workers is to regard the cancer cell produced by irritation as the *fons et origo mali*, and this has recently been very forcibly put by Sir Henry Butlin, but I am loth to accept such a hopeless hypothesis, as there is nothing analogous to it in the whole field of medicine. The forces of nature are always directed to safeguarding the individual against attacks from without which may weaken health or endanger life. To produce a cell which wars against its parent and brings about self-destruction is contrary to every law of nature.

If chronic irritation were alone sufficient to produce cancer millions of people who wear boots ought to have cancer of the little toe, which is practically unknown. It is chronic irritation, *plus* abrasion, that is required; in other words, a surface through which a pathogenetic organism may find its nidus. Then the abrasion of the middle-aged woman's plump breast by the upper edge of her corset, the eczema of the nipple, the clay-pipe sore of the lower lip, the tooth ulcer of cheek or tongue, the syphilitic and smoker's sores of the tongue, the chimney-sweep's sores of the scrotum, the burns caused on the Kashmiri's abdomina by the wearing of charcoal ovens, the chronic ulcers which become malignant, the X ray eczema leading to epithelioma—are only means of entry for an organism yet to be discovered.

A QUESTION IN EUGENICS.

I pass now from my destructive criticism of what were formerly believed to be diathetic diseases, but have been proved to be due to organisms penetrating from without, to make a few remarks on diseases of the nervous system with the object of alluding to a question in eugenics. Those who study mental diseases would have us believe that nothing is more certain than the hereditary tendency to the reproduction of nervous diseases, nor anything more disastrous than the results of in-breeding of tainted stocks. When criminals repeat their kind and recurrent forms of lunacy occur, with lucid intervals in which children are conceived only to be a burden on the rates, the State may perhaps determine to interfere to protect itself in the future.

By the kindness of Dr. F. W. Mott I show two pedigrees indicating the classes among which State interference might be considered justifiable.[4]

I do not suppose for a moment that in a country such as this, where emotion plays so prominent a part in politics, any operative measures such as have been adopted in one of the States of America, would find favour. But political ideas gradually change. The "liberty of the individual" which was for a generation a great party cry has passed into oblivion, and we have in its place the political maxim that the minority must yield in everything to the will of the majority. This would therefore seem to be a favourable time for medical men to press on the Government measures for the protection of the State against the gradual increase of lunacy, and especially of criminal lunacy.

In this relation, I would remark that the germinal organs (testes and ovaries) do not actually belong to the individual, but to the next generation. As soon as they have determined his adult form they cease to be of service in his economy; and at times prove of great inconvenience—being not infrequently a cause of disease and of death. They are given him on trust for his descendants, and so badly does he often perform the duties of trustee that the blackest of bubble company promoters may appear innocent by comparison. If this view be accepted, and I maintain it is true in every respect, there should be less hesitation in employing humane and reasonable means for protecting the race. Within the last few years, and quite by accident, it has been discovered that exposure to the X rays destroys the reproductive function of the generative organs without injury to the individual. We have therefore a humane method at our command, which is not only painless but so insidious that it might, if necessary, be applied without the knowledge of the individual. It probably also would be of service to him in assisting him to maintain his mental stability in after years.

I now leave this somewhat uninviting subject to say a few words on twins, on whom I have a few observations to record.

TWINS.

The liability to the production of twins can, I think, be shown to be hereditary. It may be due to an excessive fecundity on the part of the female, or it may be caused by a tendency to the division of a fertilised ovum, which tendency may be transmitted either by the male or female parent.

[4] One of these showed suicide in four generations and all the offspring were lunatics. The other was a subject of recurrent lunacy who when out of the asylum continued to increase his family. Altogether he had eight children, five of whom were confined in asylums.

Mr. J. A. Rooth, in describing his case of Brighton united twins, gives the following family history :—

> The grandmother of the children had four separate births of twins, as well as other children, and was herself a twin. The mother of these children was one of these twins.[5]

That is, he records four generations of twins on the female side.

The following case, as indicating the influence of the male parent, I give on the authority of Dr. Wormell, formerly head-master of the Cowper-street Schools. An intimate friend and neighbour married, and his wife on two occasions gave birth to twins. After the second birth the wife died. Subsequently the gentleman married again, and his second wife gave birth to twins. In all these cases, each pair of twins was of the same sex.

Among domesticated animals twins are encouraged in sheep, because the greater the number of lambs the greater the profit as mutton, so ewes which throw habitually only one lamb are weeded out of a flock. On the other hand, among cows the profit is from the milk, and a cow that gives birth to twins falls into disgrace and is fatted and killed for beef, because the farmer sells the milk which is in excess of what is required for the calf ; twin calves are therefore very rare. Breeders also recognise the male influence, and if many ewes throw single lambs as the result of conception to a particular ram, that ram is discarded.

Dissimilar and Identical Twins.

There are two forms of twins generally recognised. In one there has been a simultaneous, or nearly simultaneous, fertilisation of two ova, an ovum descending probably from each ovary at the same menstrual period. Such twins may differ in sex, in height, in appearance, and in disposition, presenting only the general resemblance of brothers and sisters. The other form is believed to result from the division of an ovum after all the elements for development are complete. These are invariably of the same sex and are enclosed in the same membranes. In height, appearance, and character they so closely resemble each other as to be often spoken of as "identical" twins. Shakespeare in *Twelfth Night* was guilty of confusing the first form with the second, when he founded the plot of his play on the resemblance between Sebastian and Viola, as if they were identical twins.

I am able to give some remarkable facts concerning identical twins who entered as medical students at the same date and passed the examinations of the Royal Colleges and those of the M.B. and B.S. Lond. at the same time. After the Intermediate M.B. list was published I was able to find out their numbers, and by what some might consider a curious coincidence, the totals of a large number of marks proved to be identical. The marks were made up in five columns, two for papers, and three for *viva voce* and dissections. Taken alone, too much stress must not be laid upon the fact that their marks totalled the same, as among a large number of candidates this is sure to happen occasionally. But the next table signed by 17 different teachers, signing altogether 33 times for each student, shows a uniformity which could not be the result of accident. Out of all these 66 signatures there is but one variation. One teacher put "excellent" instead of "very good indeed," terms regarded at the hospital as equivalent. In the opinion, therefore, of 17 teachers, the abilities of these twins were indistinguishable or identical.

The difference between twins developed from the fertilisation of separate ova may be emphasised by disease occurring in one whilst the other escapes. Dr. R. Hutchison exhibited at the Section for Study of Disease in Children of the Royal Society of Medicine twin brother and sister, aged a year and a half, the girl being the subject of well-marked achondroplasia, whilst the boy was healthy, a photograph of whom he allows me to exhibit. By the kindness of Dr. G. E. Shuttleworth I am also able to show a photograph of twin patients of Dr. A. Jeffrys Wood, of Melbourne, by which it will be seen that the boy is normal and intelligent, whilst the girl is a Mongoloid idiot. A third case lent me by Dr. Hutchison makes the contrast still more evident, the boy being bright and intelligent, whilst the girl shows the Mongoloid type of idiocy in a marked degree. From these cases it will be seen that neither in sex, mental development, nor tendency to disease need there be any resemblance. These are known as dissimilar twins. It will be noticed that in each of these three cases the defects fell upon the girl, whilst the boy escaped.

[5] Brit. Med. Jour., Sept. 23rd, 1911, p. 654.

MODERN VIEWS ON HEREDITY.

It is almost impossible to allude to the various defects and deformities known to be hereditary without referring to the two modern schools of research, the Mendelian and Galtonian or biometrical schools, each of which is doing excellent work in its own sphere, but can see no virtue whatever in the work of the other. To those trained in biology, the Mendelian researches offer a fascinating inducement to further study, and appear to give a rational explanation of the occurrence of variations which breed true. But the precision that Mendel was able to give to his researches by crossing peas, so that he was able accurately to predict numerical results, can never occur among human beings, since such close in-breeding and back-breeding never occur in any human community. It is, nevertheless, much to anticipate approximate results.

The study of Mendelism is essentially a study of cross-breeding ; yet when in the human race a negro unites with a white, the result is a half-caste or mulatto. So also when a European unites with an Indian the result is a Eurasian. Mulattoes united in marriage should, according to Mendelian law, segregate out into pure blacks, pure whites, and intermediates, but they do not ; they continue to produce mulattoes, and Eurasians continue to produce Eurasians. The Galtonian or biometrical school rely upon a statistical method of investigation. By collecting a large number of measurements or observations they gain material from which to deduce laws of heredity. Galton began by taking height, and maintained that what was true of one quality would probably prove true for all. His statement that half the heritage of a child is derived from his two parents, one quarter from the four grandparents, and one-sixteenth from the great-grandparents, is so well known that I only mention it in passing. Professor Karl Pearson, repeating these observations, did not find the progression so regular, but the main results were not very dissimilar. Much has been done in this school since those early days, and the probabilities of many qualities have been worked out.

It will be gathered from my critical remarks on the old diatheses that I greatly dread the effect of a predominant theory, for if we are impressed by its truth we are too liable unconsciously to accept what tallies with it, and reject that with which it does not agree. How otherwise could such giants in observation have made such extraordinary and obvious mistakes in the past ?

A PEDIGREE OF 30 YEARS AGO.

It may be interesting now to show a pedigree that I buried in the Guy's Hospital Reports just 30 years ago, because its publication was long before the modern schools of heredity came into existence. I will leave it to you to judge whether it does or does not agree with the views of modern investigators. It is a pedigree of supernumerary digits associated with two other deformities, webbing of fingers and toes and an occasional development of cleft-palate. I can vouch that every possible care was taken to make it accurate, and where there was any doubt as to sex a neutral cross was used throughout the family. The man who furnished it was also of exceptional intelligence, and he traced the deformity for us through five generations. It illustrates further three points to which I wish to draw particular attention : first, the extraordinary tenacity with which a deformity once developed clings to the stock in spite of admixture of new blood in each generation ; secondly, the frequent association of altogether different deformities in the same individual ; and, thirdly, the gradual increase of a deformity in succeeding generations, which I intend more fully to enter into presently.

These deformities were transmitted without regard to sex, and it will be noted that in two instances, where the deformity in the mother was an extra finger on each hand, the children that were deformed had extra toes on each foot and no deformity of the hands. Altogether the great-great-grandmother had 80 descendants, of whom 24, or 30 per cent., were deformed. Supernumerary digits are said to have been reproduced after amputation. Darwin gives three instances in which this occurred, and explained the recurrence as due to "reversion to an enormously remote,

lowly organised, and multidigitate progenitor." The association of webbing of the fingers and toes with supernumerary digits appears to support the correctness of this view, and to suggest reversion to some highly remote amphibious ancestor.

TENACITY OF DEVELOPMENT OF DEFORMITY.

With regard to the first point, the tenacity with which a defect or deformity, once developed, persistently clings to a stock and is repeated generation after generation in spite of new blood being infused, there are pedigrees innumerable now to prove. Cannot a defect ever be washed out in its early beginnings by normal blood? My own small studies in search of hidden deformities appear to show that their tendency is rather to increase than decline. The normal appears powerless to overcome the abnormal, or, as the Mendelians say, the deformity is dominant, and the normal recessive. The pedigrees of spade hands or brachydactyly recorded by Farabee and Drinkwater are claimed as clearly illustrating these features, the abnormal only giving origin to abnormals, and the recessive normals yielding only normals. Nettleship's pedigree of congenital cataract is also claimed as following this law, but in some cases the defect was apparently transmitted through a normal. In future the closest attention should be applied to those exceptions, as from them new facts will probably be gathered. The best illustration we have of tenacity of descent of an abnormal condition is Cunier's ten generations of night-blindness. The descent appears to have been always carried on by an abnormal; but the numbers of normal and abnormal, which should be about equal, according to Mendel's law, when an abnormal unites with a normal, show a great excess of normals above the Mendelian anticipation.

MULTIPLE ABNORMALITIES.

The frequent association of different abnormalities, apparently quite unconnected, in the same individual, is another point deserving close attention and careful study. It would seem that the developmental process having once started in an abnormal direction may fail in its complex details at many points. Mr. Jackson Clarke published a case of clubbed hand due to absence of the radius associated with macrostoma, in the first volume of the Reports of the Society for the Study of Disease in Children. In the same volume the late Dr. George Carpenter published an account of two sisters, each of whom had a keel-shaped skull, congenital heart disease, ventral ruptures, webbed fingers, and six toes on each foot, who were also mentally weak. The mother was strong and healthy and showed no deformity; but a cousin, the child of a maternal uncle, had deformed hands. In the second volume, Dr. Hutchison and Dr. Sutherland published the cases of two unrelated boys presenting exactly the same deformities in association, viz.:—(1) Congenital heart disease; (2) a rudimentary hare-lip; (3) six digits on each hand; (4) shortening of the long bones of the extremities; and (5) defective development of the gums. Many other similar cases of multiple deformities might easily be added; but I have mentioned sufficient, I hope, to stimulate research into the origin of this failure of control of the developmental process in so many directions.

GRADUAL INCREASE OF DEFORMITIES IN SUCCEEDING GENERATIONS.

The last point, to which I desire to draw particular attention, is the origin of deformities from small, easily overlooked, beginnings. I feel sure a search for these will add much to our knowledge, and it may be possible by recognising the forerunners to prevent the development of the graver deformities. Among minor deformities the crooked little finger, which can easily be shown to be tenaciously hereditary, has been treated almost with scorn by Mendelians. Professor Bateson writes:—

> This peculiarity may descend both through the affected and through the unaffected, but the affection, I believe, is like that seen in chickens whose feet may be deformed through weakness ..... Pedigrees of such peculiarities cannot be expected to give results of much positive value.

I take a diametrically opposite view, and regard these minor deformities as those from which most will be gathered in the future, regardless of whether they conform to theory or not.

Weismann's Theory.

Several families in which this defect dwells I have kept in view for years, and finding it practically confined to the middle and upper classes, I used to teach, before Weismann's theory swept the field of Lamarckism, that it was probably brought about by generations of cramping of the little finger in writing, and by gloving. The adhesion between the little and ring-finger I thought might have been brought about in the same way. But Weismann has come and gone with his theory of the complete independence of germ-plasm and body-plasm, so that the effect of environment, use or disuse, upon any part of the body is not reflected, according to his theory, in the germ-plasm, and consequently not hereditary. His theory failed to account for the reproduction of lost parts, such as the salamander's tail, which is said to have been reproduced as many as ten times after amputation, and he was obliged to admit that certain influences such as lack of nourishment might influence and modify the germ-plasm which he regarded as continuous. His theory led to a discovery of inestimable value—the finding of the chromosomes of the nucleus, their reduction to half their normal number, and the restoration to the normal number on fertilisation, half being supplied by the germ and half by the sperm cell. But his theory has probably swung the pendulum of thought too much in one direction, and though it may be true that body influences of a few generations are not evident in the offspring, when we are dealing with hundreds, thousands, or millions of generations the effects of use and disuse seem to me scarcely to be denied. Perhaps no better illustration can be quoted than the gradual changes that are taking place in the human foot. It is 23 years ago that in a lecture on anatomy I pointed out that the gradual disappearance of the little toe was getting ahead of the text-books, for whilst it had already lost one of its extensor tendons, in quite an appreciable percentage of cases one of its flexor tendons was absent also. These at best, like its bones, are diminutive and useless, and its joints are commonly ankylosed. On the other hand, the great toe had undergone extraordinary development, because the inner side of the foot is the first to catch the centre of gravity in transferring the weight of the body from one foot to the other in walking; and I ventured to predict that if the world went on long enough, in perhaps half a million of years, as the useless outer toes, being less and less employed, gradually disappeared, man might become a one-toed race.

Relation of Defective Lateral Incisor Tooth to Hare-lip and Cleft Palate in Later Generation.

From this digression, which allusion to Weismann's theory has tempted me into, I return to the crooked little fingers, and I throw on the screen a sketch showing the gradual increase of this defect in three generations. (Father's, daughter's, and granddaughter's little fingers were shown, the latter's being bent to a right angle.) It is highly probable that Nature throws out warning signals of danger in the early stages of many hereditary deformities which may be discovered if a careful search be made for minor defects among the immediate ancestors. I have only worked this out in the relation of the lateral incisor tooth to hare-lip and cleft palate, but I refer to it in order to stimulate younger observers to turn their attention to this important study, and I have one further observation as yet unpublished. My attention was first drawn to it by observing that a gentleman who as a boy was noticed to have an absence of the left lateral incisor tooth, had an only daughter who presented precisely the same defect on the same side. As this only child has never married there was no chance of proving the relation to hare-lip and cleft palate in that family. It proved, however, that the defect could be transmitted and that the transmission might be through the opposite sex. Next an infant was brought among my out-patients suffering from hare-lip on the right side. This was the fifth child of a mother aged 25. The mother's lip was perfect, but she had an absence of the lateral incisor tooth of the right side which had never been extracted and was known never to have developed. The third case was the first child of a delicate woman aged 23. The mother had absence of the left lateral incisor, which she was certain had never been extracted; her infant had left-sided hare-lip and completely cleft palate.[6]

Further observations led to the discovery that an ill-developed lateral incisor tooth might foretell hare-lip and cleft palate in the offspring. A mother who showed the scar of a hare-lip on the right side, but no defect of alveolus or palate, was found to have an ill-developed lateral incisor

[6] Clinical Society's Transactions, 1888, p. 64.

on the right side. Her first child had an extreme deformity of hare-lip and cleft palate extending from the right side. The next case was the first child of young parents who was brought for operation on a hare-lip on the left side extending into the nostril. The mother was a nice-looking woman and showed no defect in her lip; but on the left side her lateral incisor tooth presented a remarkably defective development.[7] My last observation is on a young man who was operated on for hare-lip on the right side in infancy. On examining his teeth I found that the prospective division of the palate which did not proceed (or perhaps I ought to say lack of union) had divided his lateral incisor opposite the cleft into two separate small teeth. (Photographs or drawings of many of these cases were shown by the epidiascope.)

An Address
ON
THE ELECTRO-CHEMICAL (IONIC) TREATMENT OF CERTAIN GYNÆCOLOGICAL AFFECTIONS.

Delivered at a Meeting of the Glasgow Obstetrical and Gynæcological Society on Nov. 22nd, 1911,

BY SAMUEL SLOAN, M.D. GLASG., F.R.F.P.S. GLASG.,
CONSULTING PHYSICIAN, GLASGOW HOSPITAL FOR WOMEN, ETC.

MR. PRESIDENT, LADIES, AND GENTLEMEN,—I fully appreciate the honour you have done me by asking me to address you to-night on the subject of electro-therapy in gynæcology.

INTRODUCTORY REMARKS.

Time will not permit me to go fully into the subject of electro-therapy, but I do not regret this for several reasons. In the first place, much of this treatment is purely empirical—that is to say, its value is based on experience only, and it does not therefore appeal to men of a scientific turn of mind. In the second place, much experience is required in order to get the best results from it, value at all indeed commensurate with the time and expense involved, and without this experience there is a danger of its gravitating into pure charlatanism. In the third place, the expense is too great if it is to be only occasionally employed; and for a fourth reason, the branch of electro-therapy I have chosen for our study to-night is not open to any of these objections. It requires little knowledge of electric science, is simple and not at all costly, whilst its application is based on strict scientific lines, so much so that, compared with other modes of applying electro-therapy, it may almost be said to be an exact science.

At the same time, whilst only an elementary knowledge of electricity is required for its profitable and satisfactory application, it is absolutely necessary that it should be carried out by those only who are, first, clinical physicians, and second, skilful in the diagnosis of gynæcological affections. This should make it acceptable to members of a society who show by their membership that they are specially interested in gynæcology, and presumably are experts in pelvic diagnosis, besides being at the same time practical physicians.

PRESENT POSITION OF GYNÆCOLOGY.

I think those of you who are original members of this society will agree with me that during the past generation there has been a revolution in gynæcology. It was a medical, it is now a surgical, specialty. If not entirely surgical now, the medical part of it has resolved itself into a matter of probes and pessaries, of plugs and douches. These are all very good in their way. I do not despise them; but it is sad that, when these have been tried and have failed, there is usually left only the knife. As the pathologist comes in when the physician has failed, so here the surgeon takes the place of the pathologist and removes the physician's failures. Thus medicine, through the weakness of the physician, fails in attaining its legitimate aim; the success of the surgeon is an evidence of the failure of the physician; the triumph of the former is a reproach to the latter.

I think it is time we were making a change in our mental attitude towards pelvic disease. We must anticipate and deal more effectually with the pelvic organs of women in the early stages of disease in order to keep them out of the hands of the surgeon, whose museum they were surely never meant to adorn. True, the surgeon is no more to blame than is the pathologist for removing the organs which have ceased to be serviceable, and he has, for the present at least, no need to fear that his occupation will soon be gone. There is a large harvest ripe for the reaper; there is perhaps a larger one fast ripening; whilst in many cases the canker has begun, and the road to the operating-theatre will probably be a *facilis descensus*.

TENDENCY TO CONSERVATIVE GYNÆCOLOGICAL SURGERY.

Can we as a society of humane men and women do anything to help this steady march of pelvic organs towards extinction? You may reply that surgery is steadily becoming more conservative; that healthy or even partially diseased ovaries are not now removed so recklessly. I hope this is so, though only a few days ago I observed in an official document that an ovary had been removed for "inflammation," and that two had been removed for "ovaritis." There must have been good reasons in the minds of the surgeons for this; all the same, it is to be regretted. It is less deplorable, however, than what was the case not so many years ago.

This recalls to my memory an able address in advocacy of conservative gynæcological surgery delivered in Newcastle by Professor Pozzi of Paris. When, in opposition to his views, a well-known gynæcological surgeon declared that, when one ovary was requiring removal for disease, his practice was to take away the sound one also "when he was at it," since it would in all probability become diseased. Any of you who were present on that occasion may remember the sensation which followed Professor Pozzi's application of the *argumentum ad hominem* to his critic, who, if not convinced, was certainly silenced.

I feel certain that it would be unjust to hint that the trend of late towards conservative surgery is due to timidity engendered in men by the cry of "Votes for Women." Let us hope it is due rather to increasing knowledge and increasing reverence for the distinctive organs of woman. Physicians are beginning, I find, to ask if all this operative work is to increase or to diminish in the future; and that this is not confined to pure physicians let me quote from an able and suggestive address delivered a few weeks ago by the President of the Obstetrical and Gynæcological Section of the Royal Society of Medicine, Dr. Amand Routh:—

> What (he says) is to be the future of gynæcology? Is it to continue to become more and more surgical? I think not. Is it not more than possible that in the near future some president of the section will give an inaugural address upon "Treatment Other than Operative in Gynæcology," and will base his remarks upon the wonderful discoveries being made in bacteriological, chemical, electrical, and radiographical therapeutics? Even as it is, without considering these new aids in treatment, is there not a tendency nowadays to consider ourselves surgeons only rather than a happy combination of physician and surgeon, to advise an operation because it is the easiest way to treat a case, or to operate on the rush of both hospital and private practice without previous adequate constitutional preparation of the patient?

GOOD RESULTS OF ELECTRO-CHEMICAL TREATMENT.

These are at least as strong words as I have employed, and practically amount to what, before I had read them, I had intended to say. You will observe that amongst the four "wonderful discoveries being made" he has placed chemical and electrical in the middle. I may not have wonderful discoveries to tell you of because many of you already know something of modern electro-chemistry, upon which has been based some of the work which for years I have been quietly doing in a corner of the gynæcological field; but since the results have often seemed to me wonderful, it is only natural that I should take advantage of your request to address you on electro-therapy in gynæcology; and if not to plead with you the cause of electro-chemistry at least to state my case honestly and I trust without undue bias.

If it is a Utopian idea to aim at the abolition of all pelvic disease in women it is at least a grand one; and it might well and fully justify our existence as a society. If this is an impossible consummation, however, let us do our next best, devoting, if not less energy to operations, at least more

[7] Reports of the Society for the Study of Disease in Children, 1905, p. 31.

to prevention; and where in the nature of the case this is impossible to the earliest possible arrest of the disease.

I trust to point out to you one way in which this attempt may be made. If you decide to try this, to many of you a new form of treatment, it will make your work much more interesting if you study it from the scientific side, and with your permission, Mr. President, I shall attempt to convince you that it is founded on a sure scientific basis.

SOME ELEMENTARY PRINCIPLES OF GALVANIC ELECTRICITY.

I do not think you will be offended with me—at least, those of you who have not recently been working in the department of electro-therapy—if I take it for granted that you have forgotten in the multitude of your studies much of what you previously knew of electric science, and if I, therefore, in a few words recall to your mind some of the elementary principles of galvanic electricity. As the ion plays an important part in galvanism, and as upon it are based largely the laws of chemistry, I shall first ask your close attention whilst I try to give you a mental picture of this entity, upon which is based the treatment I am about to advocate.

IONS.

Let me define an "ion" as a particle of matter, generally small, moving or capable of moving in virtue of an electric charge. It may be as large as a pith ball when charged by an electrified body or as small as a molecule of SO_3 or an atom of hydrogen; and that there are such things as ions so almost infinitely small I hope to be able to prove to you.

All solutions may be divided into electrolytes and non-electrolytes—that is, into those which are, and those which are not, influenced by the galvanic current. Examples of the former are acids, bases, and salts; of the latter distilled water, absolute alcohol, and solutions in distilled water of the following amongst others—sugar, gum, starch, pure albumin. Why do these latter refuse to conduct electricity? Simply because they contain no particles electrically charged, whereas the electrolytes are teeming with free electrically charged particles, these being the carriers of the current, and therefore called ions, which simply means goers. The electric conductivity of solutions in which these ions are is only one evidence of their presence. The special behaviour of solutions when tested for their osmotic pressure also reveals a difference. The amount of the osmotic pressure exerted by a solution is directly proportional to the number of particles in it—that is, to its concentration.

OSMOTIC PRESSURE EXERTED BY SOLUTIONS.

Suppose you place in a specially prepared porous pot a strong solution of sugar. Through an opening in a rubber stopper connect this by tubing of glass and rubber to a U-tube containing mercury; immerse the porous pot in water, and await the result; you will find in a short time that the mercury in the U-tube will be pressed upwards by the expansion of the contents of the jar through the inrush of water till a balance is set up between the weight of the column of mercury and the pressure within the jar. Let this be noted and then replace the contents of the jar with a solution half the strength of the previous one. After a few hours the mercury will be found to have risen just half as high, the pressure being in direct proportion to the number of particles, or molecules as it is in this case.

Take, on the other hand, the solution of a salt—say, NaCl—and compare the results as in the case of sugar. It will be found here that—instead of the half-saturated solution producing a rise of the mercury only half the height of that resulting from the solution of twice the concentration—it will raise the column of mercury nearly as high as did the latter solution.

Now what explanation of this have we? In the case of sugar all the particles are molecules, and these continue as molecules when the solution is diluted; whereas in the NaCl solution all the particles are not molecules, many of these having been split up—or dissociated, as the process is called—into separate particles—namely, sodium and chlorine ions, or sodions and chlorions as they are called, for they differ in nature from what is known as sodium and chlorine. These ions may join and split up again as they rush about and come into collision with each other, so that imagination may picture the molecules breaking up into atoms, these rushing about in a free state, re-uniting with changed partners and darting off again.

In both kinds of solutions the molecules have no electric charge, whereas when they become dissociated each part acquires a charge of electricity—one atom plus and the other atom minus. When they become united into molecules they lose their electric charge, the resulting molecule being neutral, owing to the union of positive and negative charges. Now, as dilution proceeds a larger number of molecules become dissociated, and so the ions increase relatively to the molecules. During osmosis each ion acts as a separate particle, adding to the osmotic pressure as much as a molecule does; and as the electric conductivity in fluids is proportioned to the number of its free ions, this is found to be greater in diluted solutions than would be the case if no increasing dissociation took place by increasing dilution.

ELECTRIC CONDUCTIVITY OF VARIOUS SOLUTIONS.

Let us take ordinary tap water, which in this town is, I find, almost as pure electrically as what is sold as distilled water. You will find that for a column of this water, six inches long and one inch in diameter in transverse section, you obtain from 50 volts about 0·2 ma. of current—that is to say, there are as many electrically charged particles in this water as will yield this amount of electricity. If the water were absolutely pure there would be no resulting current, since it would contain no electrically charged particles—that is, ions. Pure water is, therefore, a non-electrolytic fluid, its resistance to the flow of electricity being practically absolute.

Dissolve some sugar or starch in this tap water and with a similar column, and the same voltage, you will obtain no more, probably somewhat less, current, since the material dissolved has occupied some of the space previously occupied by the water with its electrically charged particles. Dilute this fluid with an equal quantity of water, and you get practically the same amount of current as before the sugar was added. The conclusion thus is that any current obtained is solely due to what ions there may happen to be in the water, none of the sugar having become ionised.

Now take the case of a similar column of a saturated solution of NaCl, and you will find that the amount of current obtained through it from the same voltage is enormous compared to that through a similar column of the water in which it is dissolved. Observe from Table I. what

TABLE I.—*Currents in Columns of Solution of NaCl from 50 Volts.*

Saturated = 36 per cent.	... 600 ma.	1/32 = 1·125 per cent.	... 140 ma
1/2 = 18 ,,	... 575 ,,	1/64 = 0·56 ,,	... 80 ,,
1/4 = 9 ,,	... 500 ,,	1/128 = — —	... 45 ,,
1/8 = 4·5 ,,	... 350 ,,	1/256 = — —	... 24 ,,
1/16 = 2·25 ,,	... 240 ,,	1/512 = — —	... 13 ,,

I have found to be the results of continued dilution in this case. You see that each dilution gives the indication of containing more free ions than would be expected from the amount of the dilution; especially is this the case in the more concentrated solutions. This relationship diminishes, however, as the dilutions increase, you will observe, till a dilution of about 1 per cent. is reached. By this time practically all the molecules have become dissociated, and with further dilutions the amount of current is practically directly proportioned to the amount of concentration.

DISSOCIATION OF MOLECULES IN DIFFERENT DILUTIONS.

Suppose in the strong solution there were in every 100 original molecules 20 dissociated, then the total number of particles for each 100 molecules would be 20 + 20 + 80 = 120 particles in all. If this be diluted with an equal quantity of water, then for each original 100 there will be left in the diluted liquid 20 separated ions and 40 molecules. Suppose that by the further dilution 10 of these molecules become dissociated, this will give of separate particles 20 + 10 + 10 + 30 = 70, and of these 70, 40 will be ions. Thus, to influence the osmotic pressure there will be 10 more particles than were in half of the original solution; whilst there will be the same number of ions as there were in the more concentrated solution; and so the same current can be obtained from the weaker solution as was obtained from the stronger if the same voltage were used.

This relative increase in the number of free ions, by further dilution, continues, as I have just remarked, till we reach the stage where there is about 1 per cent. of the saline in the solution, when practically all the molecules have evidently been dissociated; not permanently so, though at no time can there be more than the merest fraction of the molecules undissociated, since there will be occasionally reunions, but the free flight space has so much increased that these are

less likely to occur. These re-formed molecules, however, will be almost immediately broken up owing to conflict with some flying ions.

You see now how the conclusion is forced upon us that a saline solution contains, even in its most concentrated form, a large number of ions; and that by dilution the number of these has become relatively increased; *quod erat demonstrandum*.

To Arrhenius, of Sweden, we owe the placing of the dissociation theory of electrolysis on a sound experimental basis. To our own Faraday we owe the laws of electrolysis; whilst to Professor Leduc, of Nantes, belongs the honour in a pre-eminent degree of applying these discoveries in the service of medicine. Leduc is a man of transparent modesty, he is a charming personality, and it has been a pleasure to me to know him. For fuller information on the subject I commend to you his book on "Electric Ions and their Use in Medicine."

GALVANIC CURRENT.

We have seen how a galvanic current passes through an electrolytic solution in virtue of the ions existing in it, no ions meaning no electric current. I should like to point out, however, that not only is this the case, but the energy which has come from the battery is derived from ions existing in the cells of the battery.

If you place a piece of zinc on the one side of the tongue and a piece of copper on the other, you will find—if these plates are connected by means of copper wire with a galvanometer interposed in the circuit—that a deflection of the needle takes place as soon as the metals are placed in the mouth. Taking the ions of the saliva as NaCl only, you will observe from the diagram what chemical change takes place in the mouth when the circuit is completed; and if you try the experiment upon yourselves you will find that, with the formation of HCl at the zinc plate, an acid taste is distinctly felt at that portion of the tongue on which the zinc rests.

The cause of the migrations of these ions between the two plates, as you will see from the diagram, is that the copper plate has—as represented in the diagram—negative electrons attached to it, and the zinc plate positive electrons. These electrons do not travel across the fluid to neutralise each other; neither do they pass round the metal circuit in order to become neutralised; but they remain fixedly attached to the plates, indicating a state of elastic electrical tension existing between them—that is to say, they have relatively to each other a difference of potential. The electric charge on them acts only by attracting or repelling the different ions in the saliva; the positive ions being attracted to the negative copper plate, and the negative ions attracted to the positive or zinc plate.

As I have said, these do not, when they reach these plates, influence the electric charges of the plates by neutralising them, but may be said to accumulate at the junction of the wire and the plate—positive electrons at the junction of the copper plate, and negative electrons at the junction of the zinc. Thus is made plain what is difficult at first to understand—that, whilst the copper plate is negative, it is in contact with the positive pole of the cell, the zinc plate, which is positive, being in contact with the negative pole of the cell. So long as the wires attached to the plate remain unconnected the electric charges on each of them—plus and minus—cannot unite. This is shown in the diagram, whilst there is also depicted the circuit completed through a galvanometer.

When the circuit is completed these electrodes are capable of revealing their presence in two ways—first, by heating the connecting wire if it is thin enough or if the battery is powerful enough; secondly, by being able to deflect the needle of a mariner's compass if the wire through which the current is passing is held over or under it. The direction of the deflection of the needle from the north pole depends on the direction of the current at the time. The current has thus direction; it has polarity, and so we call the terminals of the wires poles.

GALVANIC BATTERY.

This is the principle of all galvanic cells, and in order to increase their power we join them into a row, connecting the minus pole of the one to the plus pole of the next in order, and so obtain an electric pressure in direct proportion to the number of cells we employ. This electric pressure we call electro-motive-force, and we calculate it in volts, each cell being equal to about one or one and a half volts, according to its construction.

For ionic purposes from 20 to 40 cells are required, yielding a total voltage of from 20 to 50. This voltage is not galvanic electricity; it is electric potential or static electric pressure. It becomes current, however, when the separated ends are joined, and it can then display its effects, thermic, magnetic, and electrolytic.

The amount of current which a given voltage can generate is determined by the difficulty or friction it has to overcome in order to complete the circuit. If there be much difficulty, or resistance as we call it, then the yield of current or actual (kinetic) energy is less, and *vice versâ*. The ratio is $\frac{E}{R} = C$, where E is the electro-motive-force, R the resistance, and C the current. As E is calculated in volts, so R is calculated in ohms, the current being measured in ampères, and a coulomb being one ampère-second. For ionic medication, however, our galvanometers register thousandth parts of an ampère—that is, milliampères.

Through some conductors of electricity the current passes with very little difficulty—silver and copper, for instance, if pure and moderately thick, have extremely little resistance; whilst others, such as platinum and the element carbon, especially if of a very small cross section, cause a very considerable amount of resistance, and therefore of heat. This, in the case of the platinum, is utilised in the galvanic cautery; whilst carbon is employed as graphite to restrain the current, where, with the given voltage, the amount of current would be in excess of the requirements. When so used it is called a rheostat.

The choice of a suitable battery and a suitable rheostat is not a very important one. Convenience and price may be permitted to determine this. I find the Leclanché cells and the graphite rheostats satisfactory, though the latter are less safe than more expensive ones, for the gradual and steady increase of the current by the rheostat is apt to suffer if this is at all out of order, and for the comfort of the patient and the peace of mind of the medical man sudden increase or decrease of the current is to be deprecated.

QUESTION OF VALENCY.

We have hitherto been considering ions as having one electron charge only. As you will see from Table II., some

TABLE II.

Element.	Atomic weight.	Valency.	Electro-chem.-equiv.
H	1	1	1
O	16	2	8
Cl	35·5	1	35·5
I	127	1	127
Cu	63·5	2	31·7
Zn	65	2	32·5

ions carry two; and though others carry three or more the chemicals likely to be used in ionic medication are either monovalent or divalent—that is, they carry one or two electrons. They are therefore called monads and dyads. From this table you will see that the valency of oxygen is 2—that is, it carries two electrons. It is thus, in the case of water, able to neutralise the two electrons of H_2; and so in $CuCl_2$ the Cu is divalent so as to neutralise the two Cl electrons, and thus form a neutral molecule. This, you will find, must be recognised when calculating the total of a substance transferred by ionic penetration.

KATIONS AND ANIONS.

Note that the electrons are given up at the poles only, where, having lost their electric charges, they assume their ordinary qualities—two atoms of the same element uniting to form an ordinary molecule of that substance as we know it in nature, or they may as atoms attach themselves to one or more of the atoms of the molecule water, and thus cause decomposition of the water. So great is the attraction of the hydrogen and oxygen in water that to tear them asunder in this way requires nearly two volts. These electrons are discharged always as one atom of electricity, as they are considered to be, or as a multiple of one; never a fraction of one. They are therefore indivisible, like the atoms of ordinary matter.

Those ions which, being charged with positive electricity, and therefore travelling towards the negative pole, are called kations—that is, cathode travellers; the other anions, or

anode travellers, seeing that they migrate in the direction of the anode or positive pole. That is, these ions are repelled from the pole which has the same sign as themselves and are attracted to the pole of opposite sign. The kations are called electro-positives and the anions electro-negatives. You will find in Table III. examples of some of these; those only, however, in which we are at present interested.

TABLE III.—*Examples of Kations and Anions.*

Electro-positives (kations).		Electro-negatives (anions).
Cu.	Cocaine.	Cl.
Zn.	Strychnine.	I.
Quinine.	Atropine.	Salicylic acid.
		Sulphurous acid.

CALCULATION OF IONIC PENETRATION.

You are all familiar with what is meant by atomic weight in chemistry, and I have pointed out that some atoms carry one, some two, electrons or atoms of electricity. Now it will be obvious that twice as much electricity will be given up at the electrodes in the case of the latter as in the case of the former; and, according to the laws of electrolysis, the amount of ions displaced is directly proportioned to the amount of current registered during the process.

The electro-chemical equivalent, therefore, will be found to be the atomic weight divided by the valency—that is, by the number of electrons with which the ion is charged. In the case of the monads the electro-chemical equivalent will be the same as the atomic weight; whereas in the case of the dyads the electro-chemical equivalent will be the half of the atomic weight. Now, as one coulomb, that is one ampère second, is capable of displacing 0·0000104 of one gramme of hydrogen, or this amount multiplied by 108 in the case of silver—this being the atomic weight of the latter—and as the total amount of ions displaced or transferred into the tissues is equal to the product of the number of coulombs of electricity passed, multiplied by the electro-chemical equivalent of the substance, multiplied again by the amount of hydrogen displaced by one coulomb, the total amount of ionic penetration can thus be calculated.

For example, the total weight of the ions introduced from 20 ma. for 15 minutes—that is, from 18 coulombs—equals

$0{\cdot}02 \times 60 \times 15 \times 0{\cdot}0000104 \times 31{\cdot}7 \times 15{\cdot}5$ (grains in 1 gramme) $= 0{\cdot}1$ grain.

This gives no idea, however, as to the number of ions which this weight may imply, and before we can even in imagination conceive of this it is necessary that we should know the size and weight of the ultimate atoms of matter. All atoms may be considered to be of the same dimensions—at least, that is the present belief—and this dimension is given as 10 raised to the power of minus 8 of a centimetre (10^{-8} cm.); that is to say, a ten-millionth part of a millimetre. The weight of an atom of hydrogen is 10^{-25} of a gramme—that is, the ten-quadrillionth part. The weight of an atom of oxygen will therefore be 16 times that, the weight of an atom of copper 63 times that, and so on, being the weight of an atom of hydrogen multiplied by the atomic weight of the particular substance. It may be interesting to know that the weight of an atom of electricity has been calculated as the 700th part of the weight of an atom of hydrogen and its linear dimension about the 100,000th part.

RELATIVE NUMBERS OF IONS AND GERMS.

You will observe that I have calculated the medicinal dose of copper ions in gynæcological practice as about one-tenth of a grain. It may appear to you that the mountain having been in labour a very small mouse has been born; but think of what this small fraction of a grain means, if you are capable of thinking in such minute fractions. It means 1000 millions of millions of millions of ions of copper. It is even more difficult to grasp the meaning of this than to appreciate the practically immeasurable distances of some of the stars in infinite astronomical space.

Now the object of the introduction of these ions into the tissues in gynæcology is the destruction of the armies of the septic fiend. You are accustomed to look on these microbes as the infinitely little, and so you may, perhaps, be able to imagine what this fraction of a grain may do in this warfare when I tell you that it would be capable of introducing into each of a million million millions of streptococci a garrison of a thousand ions with abundance of elbow-room for each ion.

COMPARISON OF ELECTROLYSIS AND IONIC MEDICATION.

Some of you are more familiar with the term electrolysis, in the application of electricity to gynæcology, than with ionic medication. These two terms signify the same thing from the point of view of physics. For therapeutic application, however, they are exactly opposites. In electrolysis the aim is to utilise the effect of the ions when they reach the electrode; in ionic medication, on the other hand, it is the ions which leave the electrode that are utilised in the treatment.

The application of chemicals to any part of the mucous membrane or the skin results in the absorption of the substance dissolved; this we might call osmotic diffusion. This process is also in action during the application of ionic medication, but with this difference, that whilst in the case of the former the fluid passes into the capillaries and lymph channels as soon as it has reached them, and then finds its way into the general circulation, in the case of ionic penetration besides this there is a steady march of the ions right through the tissues—not going round the cells but straight through into the protoplasm of the cells and remaining there. This it is which gives the ionic treatment its peculiar therapeutic properties.

The choice of the suitable pole for the active electrode is of importance both in electrolysis and in ionic medication. In the former, if astringent and caustic effects are desired the positive electrode must be applied. If softening and breaking down are required the electrode applied to the negative pole must be the active one. But in either case the effect is due not to any extrinsic ion but to the ions of the tissues.

In ionic medication, on the other hand, it is more a question of the chemical to be employed, since to it is practically wholly due the effect produced. The decision as to the pole to be employed is determined simply by the electric charge on the ion selected. Electro-positives are driven into the tissues by the positive pole, as might be inferred; electro-negatives from the negative pole. In electrolysis a non-electrically soluble electrode is employed, such as platinum or carbon; in the case of ionic medication the electrode is the substance whose ions it is intended to introduce where this is possible.

PHYSICS OF ELECTROLYSIS.

I show you now a series of U-shaped tubes illustrating the physics of electrolysis, osmotic diffusion, and ionic penetration respectively.

In the tube containing the solution for illustrating electrolysis there is contained in solution iodide of potassium, starch, and a few drops of phenol-phthalein, the object being to prove the migration, in the solution, of the ions of iodine to the positive pole and of the potassium ions to the negative pole. When the iodine becomes un-ionised by contact with the positive pole it will produce the strong blue colour of iodide of starch. When the potassium yields its electrons at the negative pole, being unable to exist in water as a metal, it will combine with hydroxyl extracted from the water molecule, setting the remaining atom of hydrogen free as a gas, and changing the phenol-phthalein into a distinctive red colour, indicating the presence of an alkali.

OSMOTIC DIFFUSION.

In the case of the U-tube containing the solutions to illustrate osmotic diffusion solution of common salt may be introduced into the tube, and on the top of this in each limb say a solution of methylene blue to the extent of about one inch in depth. If these added coloured solutions are denser than the solution of salt in the tube they will almost at once be diffused down the column of water by gravity. If of exactly the same molecular concentration they would practically never change their position. A degree of concentration less than the salt solution is therefore chosen, and, given sufficient time, complete diffusion will result.

The next U-tube contains the same as the middle one, but to each limb has been attached an electrode from a battery of cells. The experiment in this case was begun just before the hour of meeting in order that sufficient time might elapse to show the effect produced.

In the diffusion tube a slight extension downwards of the colouring matter in diminishing depth of colour is seen, but the deepest hue of colouring is at the very top. In the case

of the electrically treated tube, however, there is a difference: the junction between the coloured and the uncoloured solutions remains sharp. The upper part of the coloured portion, moreover, is not now at the highest part of the fluid in the limb of the tube to which the electrode from the positive pole is attached, there being a depth of colourless liquid of about a quarter of an inch in this case at the upper part, the current having driven the ions of the coloured fluid to that distance from its original position. In this case the total length of the coloured fluid, however, remains the same.

IONIC PENETRATION.

I show you in two tubes examples of ionic penetration, compared with ordinary diffusion, through a piece of the wall of the fresh stomach of the ox, the animal having been killed a few hours only before the experiments.

In these two specimens a solution of $CuCl_2$ has been placed on the mucous surface of each piece. In the simple diffusion case after five hours the copper had absolutely failed to enter into the mucous membrane, there being only a slight colouring on the surface, easily washed off.

In the case of the specimen under the same conditions in the other tube a current of 5 ma. during five hours has been passed through the copper solution and the tissue from the positive pole, the total current being thus 90 coulombs, or about five gynæcological doses.

You will find under the microscope on the table a section of this specimen. The report from Dr. Leslie Buchanan, who kindly made the sections for me, is as follows: "That which was subjected to ionisation is readily distinguished by having a portion of bluish-green colour highly condensed and fairly firm in comparison with the rest of the tissue. The cut surface of this condensed portion shows a greenish colour to about half its thickness [the total thickness of the tissue is 6 mm.] and exposure of the cut surface to a solution of sulphide of ammonium results in the conversion of the greenish colour into a very deep brown or almost black. The portion treated simply by diffusion shows no change from the normal either in colour or texture. Sections prepared for the microscope show that in the case of the ionisation the metal has passed through the mucous membrane and submucous tissue and lodged in the tissue of the muscle below. The metal is exceedingly finely divided, and is manifestly lodged in the tissue, not simply deposited on it—i.e., the metal is intra-cellular, not simply inter-cellular. It is evident that the mucous membrane has opposed considerable resistance to the passage of the metal, as a large amount of it is deposited on the surface of the tissue in addition to what has penetrated. In the case of the diffusion no metal is found either by the microscope, or by change of colour with ammonium sulphide, in the tissue itself."

COMBINED ELECTROLYSIS AND IONIC PENETRATION.

I have here a piece of flesh meat, and I can show you by means of it an example of combined electrolysis and ionic penetration. I push an electrode of copper and one of platinum into the tissues, attaching the copper probe to the positive pole and the platinum to the negative. I am not placing them too far apart, since I have here only a small electro-motive-force to work with, and so I am diminishing the resistance and thus increasing the current.

We will allow the current to remain in action for about 15 minutes, and you will find at the end of that time that the platinum probe is easily lifted out of the tissue, for the reason formerly mentioned, whereas the copper is adherent, since the O and the HCl which have separated at the positive pole out of the NaCl and the H_2O of the tissue have coagulated the albumin of the meat around the electrode. If the action is allowed to continue sufficiently long a severely caustic action will be produced.

These are the results of electrolysis; but something else has taken place as well. If you examine the part where the copper was you will find that the HCl resulting from the electrolytic action has gradually dissolved some of the metal, and the resulting copper ions have travelled a certain way on towards the negative pole. This is ionic penetration. If the process had been allowed to continue sufficiently long it would have been impossible to remove the copper rod without tearing away some of the flesh. In that case, if the current be reversed for a few minutes, the copper being thus attached to the negative pole, sodium ions will come to it; the tissue will be softened and the copper can then easily be lifted out.

If by this time you are coming to the conclusion that I am over-estimating the importance of ions, let me point out to you what I mentioned in proof of the fact that in a solution of 1 per cent. or less of NaCl practically all the particles were ionised. Now the salines of our body are in a concentration of about 0·9 per cent., so that all the salts in our tissues must be present as ions; and since all vital action is accompanied by electric change, and no chemical alterations can take place without these electrically charged bodies, life must be impossible in the absence of ions.

ACTION OF CHEMICALS ELECTRICALLY DRIVEN INTO THE TISSUES.

I have said that all vital action is accompanied by electric change, and therefore by electric currents, since, whenever there is a difference of potential in the presence of ions, a current must result. Now Pauli, in his book "Physical Chemistry in the Service of Medicine," states that "differences in the concentration of ions brought about through [bringing about?] differences in their migration velocities constitute the source of differences in the electrical potential."

That this was true I had long hoped, since it would explain what to me had formerly been puzzling—namely, how was the chemical, which had been electrically driven into the tissues, and had then assumed an insoluble form as in the case of copper—how was this to be disposed of, and how could it in that form act therapeutically? For more than a year I have, by means of a very delicate mirror galvanometer, made many attempts to prove or disprove this. I asked an expert in electro-physics and one in electro-therapeutics to join me in the investigation, with the result that we all came to the conclusion that this statement was not true. However much it might be true to others it, therefore, had to remain to me untrue.

Recently, however, I again attacked the problem and discovered that, though not true, it was yet a half-truth. No matter how great might be the difference in concentration of contiguous saline solutions, no current could be observed. I noticed, however, that there was sometimes a slight deflection of the needle at the moment of insertion of the platinum wires, but this current immediately stopped when the wires were at rest in the solutions. This led me to the conclusion that the difference in concentration alone was not sufficient to cause a current. If, however, whilst the wires were at rest and dipping into solutions of widely different degrees of concentration, the fluid was then shaken, at once and on every such occasion a marked amount of deflection of the galvanometer needle ensued. Therefore, there is a difference of potential and a resulting current, but only when there exists at one and the same time a difference of concentration *and a flow*.

Since then this is exactly what exists in a greater or less degree throughout living organisms, there must in and around the deposited insoluble powder (in the present case the insoluble oxy-chloride of copper) be constant, though weak, galvanic currents, and consequently some degree of dispersion of the substance by galvanic action. These vital electric currents, which are continually in action, will therefore continue to carry on the work and thus cause the diffusion and final removal of this apparently inert powder by means of ionic migration.

I find that the more the disturbance of the solutions of different degrees of concentration the greater is the current generated. Every muscular movement, therefore, must assist in the diffusion of the substance introduced into the tissues, even when it has been rendered insoluble by the action of the oxygen and chlorine of the tissues.

SELECTION OF CASES AND ION.

In the selection of a suitable ion, one must be guided by the nature of the case. The object of the treatment is to remove sepsis and the accompanying inflammatory exudations. Cases of acute inflammation, of threatened suppuration, and, *a fortiori*, cases of actual pus formation, and also cases of cystic disease are absolutely unsuitable. Apart from these unsuitable cases, however, there remains a very large number of gynæcological affections hitherto treated in a more or less perfunctory manner because with very little hope of permanent benefit. Is it not possible, however, may I venture to say is it not almost certain, that nearly all of those

pathological conditions unsuitable for this treatment might have been prevented if ionic medication had been applied in time and in a thorough manner?

As to curettage, the nature of the case must determine the wisdom of doing this before trying the ionic treatment. This operation is not excluded, but I have found it, since I began the method I am advocating, very seldom necessary.

THE IODINE ION.

When the affection partakes at all of a subacute nature I prefer to start with iodine as the ionic agent. Iodine being electro-negative, the minus pole must be the active one, and the electrode there should be a carbon one, such as I show you. There is no advantage in applying the iodine wholly in an uncombined form, because, as you will observe from one of the diagrams, it at once becomes converted in NaI when it enters into the tissues. The solution I employ is a 2 per cent. one of iodide of potassium combined with 0·2 per cent. of liquor iodi.

The iodine ion will reach the cellular tissue of the pelvis by diffusion, whilst it will penetrate electrically into the protoplasm of the tissues which it has reached during the process of diffusion. I find that it can be detected in the saliva 25 minutes after the beginning of the application, whereas by diffusion alone it takes several hours to reach the mouth from the vagina.

Where there is inflammation of the tubes, the ovaries, or the cellular tissue, if no suppuration is present the iodine ion has given me good results. I am bound to admit, however, that I do not confine the treatment to ionic applications in these cases, but usually finish off with some other form of electric energy, usually the high frequency. Therefore it may be difficult to determine the relative value of these two forms of electro-therapy. The high-frequency currents may be able to complete the cure, but I am certain they can never destroy sepsis as ionic medication can.

Of the *mercuric ion* I have no experience. It is said to have been very serviceable, however, in cases of malignant disease when the diseased tissue is within reach. In such circumstances, however, the dose is enormous and the treatment necessitates the administration of chloroform.

ZINC AND COPPER IONS.

If the case is one of simple cervicitis then the zinc or copper electrode, covered with cotton wool, is inserted into the cavity of the cervix through the speculum, which is filled with a 1 per cent. solution of the bichloride of the metal employed.

When the endometrium is involved the zinc electrode should be introduced into the uterine cavity, and if insufficient action result, or the case be a very chronic one, the copper electrode must be used. It should be remembered, however, that the latter is more likely to cause pain and bleeding, as might be inferred from the meat experiment made. The zinc electrode, however, comes away easily and without the necessity for reversing the current.

In cases of prolonged uterine hæmorrhage the copper will be found the more potent electrode, although, where the patient is very sensitive or there is any reason to fear pelvic cellulitis, it is well to avoid the use of the bare copper electrode. This at least has been my experience.

Either the zinc or the copper can be used with perfect safety in solution by means of the speculum in all cases of sepsis of the cervix. Before an electrode is introduced into the cavity of the uterus, however, the vagina and the cervix must have been rendered as far as possible aseptic by ionic treatment if necessary, after which with moderate care no harm can result from the intra-uterine application.

DESCRIPTION OF INSTRUMENTS.[1]

My first difficulty was with electrodes. I have had some made, however, which give me every satisfaction so far as convenience goes; and this is more important to the physician and to the patient than might be at first imagined. I have had a glass speculum made which suits much better than the ordinary one. It has openings in it near to the cervical end, thus partly distending and filling the vagina.

The holder of the electrode is kept in position by a bag of shot which rests on its broad end on the couch, the patient being on her back with a bed slipper under the pelvis. This holder, as you will observe, keeps the speculum in position, preventing it from slipping out or from dropping. Everything being fixed, the cervical or intra-uterine electrode can, after inserting it through the speculum, be kept in position with perfect ease and safety.

A spiral of copper wire or of zinc, as the case may be, inserted into the speculum and fixed to it in the way shown in the plate, serves for vaginal applications, and also for vulvar by using it for the purpose of pressing against a pad of cotton wool soaked in the fluid and packed carefully against the open vulva.

METHOD OF APPLICATION.

In order to avoid shock the current should be started and stopped slowly and steadily. I formerly applied the neutral electrode to the hypogastrium or to the sacral region, but this involved the undressing of the patient and prevented the current from being diffused equally throughout the cavity of the uterus, since it takes the most direct course to the neutral electrode. I find the hands a convenient place for the application of this electrode—a large clay one—because, being at a distance from the uterus, the current will more readily diffuse itself over the whole of the uterine wall. All rings must be removed whilst the current is flowing, otherwise the fingers may be burnt beneath the rings.

No pain need accompany or follow the application when the method I now follow is adopted; but in some of my early cases considerable pain, and in two instances some pelvic cellulitis, followed. No permanent injury, however, resulted.

I prefer to obtain the current from a battery instead of taking it by a shunt circuit off the electric main. The latter, in my opinion, is less safe. I show you a vulvo-vaginal electrode, which is relatively more troublesome to use; but in cases of combined vulvar, vaginal, and cervical sepsis it will give results well worth the trouble as a preliminary to deeper applications.

CLINICAL RESULTS.

It would only weary you to give clinical details of the cases which I have successfully treated by this method. You can find fairly full details of these in THE LANCET of July 10th, 1909, and Feb. 5th, 1910. Suffice it to say that the cases have been as a rule obstinate, but not in the sense of being obscure, difficult to diagnose, or fit for treatment by the gynæcological expert only. Far from being so, they were all such as the general practitioner is probably treating every day in his practice, and if he is satisfied with my results he can easily carry out the treatment for himself.

When the patient has given a fair chance to the treatment all the septic cases have benefited in a manner gratifyingly monotonous. The discharge, from being purulent or muco-purulent and copious, has become milky and of small amount, whilst the gaping os has become normal in size with the everted mucous membrane drawn in, and erosions have healed with a rapidity which was a revelation to me.

That the general health invariably improved coincidently with the cure of the septic condition and that the tongue, which in some cases had been foul for years owing to auto-toxæmia, should without any gastric treatment become clean and remain so is one of the evidences of this constitutional improvement. In two of my cases this toxæmia was accountable for periodic attacks of severe gastric pain, due evidently to the effect of the toxæmia on the solar plexus. In one of these cases, where the pain had lasted for 12 years, this was completely removed after a few intra-uterine applications of the copper electrode. This was several years ago, and there has been practically no return of the pain since.

In cases of long-continued retro-displacement of the uterus I find that, whereas under ordinary treatment a pessary has had to be worn for many years, this instrument may become unnecessary after a course of ionic medication, the uterus resuming its normal position in the pelvis and remaining there. Patients whom I used to treat periodically have been apparently perfectly and permanently cured. Though under my observation for years after, the pelvic condition has required no attention. This has been to me a new experience since I have adopted the ionic treatment, and so I invite you to try it. That it will give you satisfaction I have no manner of doubt.

The special instruments are here for your inspection, and for fuller details I refer you to my published papers already mentioned. I thank you for your patient attention to my address, and I trust I have succeeded in interesting you.

[1] These instruments are described and illustrated in THE LANCET of July 10th, 1909, p. 72.

A CASE OF RUPTURED ŒSOPHAGUS.

BY D. W. ROY, M.A., M.B., B.C. CANTAB., F.R.C.S. ENG.,

LATE SENIOR RESIDENT MEDICAL OFFICER, ROYAL FREE HOSPITAL; AND HOUSE SURGEON, ETC., ST. GEORGE'S HOSPITAL.

A MAN, aged 43, a shunter, was admitted to the Royal Free Hospital on July 31st, 1909, at 3 A.M. He was suffering from a severe compound fracture of both bones of his right leg. The accident occurred in the following way. He was conducting shunting operations at night. After uncoupling a carriage in motion, he endeavoured to spring on to the footboard, miscalculated the distance, slipped, and fell, the wheel running over his right leg.

On admission to hospital he was conscious and able to give an account of his accident. He was slightly dazed, but not suffering much from shock. His temperature was subnormal; his pulse 100 and of good volume. He did not complain of any symptoms referable to any other part but his right leg. His right leg was very severely crushed in its lower third, being practically a bag of bones held by the skin and some tendons. It was obvious that there was no hope of saving the limb, so amputation without delay was decided on.

The patient was anæsthetised with A.C.E. mixture and his leg was amputated by Farabœuf's method at the site of election. During the early part of the operation he did not take the anæsthetic well, and strained and retched violently enough to cause defæcation to take place and to interfere with the preliminary cleansing of the limb. He brought up a few mouthfuls of a brown fluid. From this time till the end of the operation he was rather cyanosed and embarrassed in his breathing. Owing partly to this delay the operation lasted about 1¼ hours. The patient was suffering considerably from shock when removed to the ward. He was cyanosed and sweating freely; his temperature was 97° F., his pulse 120 and small in volume, and his respirations 40. He was given one pint of saline solution per rectum, and the foot of the bed was raised. He came round partially from the anæsthetic, and moved his limbs but did not speak.

At 10 A.M. the patient's breathing suddenly changed in character. He was still cyanosed but now deeply unconscious and breathing stertorously; his pupils were moderately dilated, slightly unequal, and reacting sluggishly to light. The corneal reflexes were very faintly marked; neither the knee-jerk nor the plantar reflex on the sound side could be obtained. There was nearly complete flaccidity of the limb. The temperature was 101°; the pulse 118, of moderate tension, and fairly full. A catheter was passed and urine drawn off and examined. This was found to contain neither sugar nor albumin. The skull and spine were again carefully examined, but no external sign of injury could be discovered.

Mr. E. W. Roughton now saw the patient and decided that, considering the history of the accident, a decompressive operation might be of value. The patient was taken to the theatre and a crown of bone was removed from the left occipital region. The dura mater was normal and was not opened; there was no sign of raised intracranial pressure. No anæsthetic was needed, the patient showing no sign of reflex movement during the operation. The patient's temperature on his return to the ward was 103°, his pulse 120; he remained cyanosed, stertorous, and deeply unconscious.

When seen again at 4 P.M. the same afternoon he exhibited rather a remarkable condition which was difficult to account for at the time. He was partly propped up in bed, and with each expiration was projecting from his mouth to a distance of 3 or 4 feet a finely divided spray of a brown fluid, of which there seemed to be an endless supply. This dark fluid, speckling the counterpane almost at the foot of the bed, at once caught the attention. This continued for some hours until the patient's breathing became feeble. His condition was evidently hopeless and he died at 3 A.M. on August 1st, 24 hours after admission.

Necropsy.—The post-mortem examination took place on August 2nd, 31 hours after death. The skull was normal, with the exception of the trephine hole in the left occipital region. There was no fracture or dislocation of the vertebræ either in the cervical region or elsewhere. The meninges were normal to the naked eye, showing no hæmorrhage or other vascular lesion. The brain was congested, but as far as naked-eye appearances went was otherwise normal both externally and on section. The stomach contained a small quantity of acid-smelling fluid. All the abdominal viscera were normal. The operation wounds and the stump of the right leg were healthy. There was no subcutaneous emphysema of the chest wall or neck. When the incision made in the throat to remove the larynx and œsophagus reached the base of the neck, the cellular tissue to the right of the œsophagus was seen to be infiltrated with a dark brown fluid. On opening the thorax the fluid could be traced down in the posterior mediastinum to a spot in the œsophagus about 3 inches above the diaphragm. On opening the œsophagus a hole easily admitting a large probe was found at this level, posteriorly and somewhat to the right of the middle. The opening was ragged and discoloured but showed no sign of corrosion or thinning of mucous membrane round it. Except for the opening described, the mucous membrane of the œsophagus appeared smooth and normal. On removing the œsophagus it was seen that there were two roughly circular areas, each of about the size of a shilling, where the wall was considerably thinned, but thinned at the expense of the outer muscular and connective tissue coats chiefly. It was through the lower of these two areas that perforation had taken place. The other area was about an inch higher up and more directly in the posterior wall of the œsophagus. Opposite to these thin places and projecting quite half an inch from the thoracic vertebræ were two very sharp irregular exostoses which seemed to be exaggerations of the normal lipping. No preparation had been made for demonstrating a pneumothorax, so its existence remains uncertain though probable. The right pleural cavity contained about half a pint of acid-smelling fluid slightly blood-stained but otherwise resembling the stomach contents. Both lungs were œdematous and congested; the right lung was partly collapsed. The trachea and upper part of the bronchi showed traces of the brown fluid, but the smaller bronchi were free from it. The heart and pericardium were normal. The fluid from the pleural cavity and the stomach and the intestinal contents were examined by Dr. L. Freyberger. The first two were reported to be gastric contents containing traces of pickles. No abnormal constituents were discovered. Unfortunately no portions of the brain were examined microscopically or stained for fat, and the specimen of œsophagus was not recovered from the analyst.

Remarks.—Cases of ruptured œsophagus are among the rarities of medicine, only 30 cases having been recorded up to 1903 as passing the criticism of authorities. Many cases have been rejected as examples of post-mortem digestion. The claims of this case to be regarded as an ante-mortem condition are pretty strong. The absence of any sign of digestion or erosion of mucous membrane round the perforation, the fact that the perforation had taken place through one of two areas where the muscular coats were thinned or deficient, and the presence of gastric fluid as high up in the mediastium as the root of the neck are all in favour of this contention. The continued respiratory embarrassment noted after the retching, with the disproportionate shock after the operation and the remarkable respiratory condition seen a few hours before death are susceptible of explanation from the post-mortem findings. One would explain the projection to a distance of the finely divided spray of stomach contents, which exactly resembled the intermittent blast of a throat spray with a single bellows, by analogy with that instrument. Assuming that the cardiac orifice was closed, the œsophagus as far down as the perforation could act as the vertical tube of the throat spray, and the extravasated fluid in the posterior mediastinum and right pleura could be gradually aspirated up into the œsophagus in a finely divided state, mixed with the air that almost certainly would find its way into the pleural cavity. When this material reached the level of the larynx, the forcible expiratory movements of the lungs could act as the bellows of the throat spray and propel the particles to a distance. The expiratory movements of the chest, by increasing the intrapleural pressure, would assist fluid to pass up the posterior mediastinum towards the neck as well as through the opening in the œsophagus if that remained open.

As to the causation of rupture of the œsophagus, excluding cases where there is some gross injury of the parts around from accident or from the extension of tumours, in nearly

all the cases there is a history of more or less violent straining or vomiting. This cause was not absent here, but it operated while the patient was under the anæsthestic.

The experiments of Mackenzie [1] and some incomplete experiments made by Bowles and Turner [2] have shown that the posterior wall of the œsophagus in its lower third is the weakest part, and that here the œsophagus is unexpectedly easy to distend, or even to rupture.

McQueeney [3] has described a condition of inflammatory softening with round-celled infiltration in this situation, and supposed that in certain cases this was a predisposing cause.

Zenker and Ziemssen [4] consider that an intra-vitam œsophagomalacia, due to the retention of acid and peptic material, can take place even in apparently healthy individuals.

Brosch,[5] quoted by Whipham, and other observers have noted the occasional partial absence of muscular fibres in this situation.

In the present case two areas of thinning of the muscular coats were seen; but it seems probable that they were not unconnected with the presence of the sharp exostoses of the thoracic vertebræ, and may have been caused by the pressure of boluses of food in their passage down the œsophagus. The accident which caused the original injury to the leg, combined with the sharp exostoses, may have caused a rupture of some fibrous tissue at the seat of perforation, but the absence of symptoms or of shock precludes the presence of any extravasation when the patient was admitted to hospital. Extravasation apparently took place when the patient strained violently under the anæsthetic. The symptoms in this case, as in one described by Whipham,[6] were masked by a superadded cerebral condition which caused unconsciousness. The only sign noted was the projection of the brown spray previously described. Subcutaneous emphysema was absent in this case, as in 3 out of 19 cases in which it has been looked for. A pneumothorax, probably present in this case but not proved, has been noted in 16 out of 19 cases described.

The diagnosis in this case was not made during life and in the presence of another condition causing coma was not suspected. The actual cause of the coma and death of this patient was never certainly ascertained. In the absence of evidence of any gross lesion of the brain or meninges, of uræmic or diabetic coma, or narcotic poisoning, one was left to consider the question of a late anæsthetic effect or of fat embolism of the brain. The anæsthetic employed was the A.C.E. mixture given by a skilled anæsthetist in moderate amount, so that it is possible almost to exclude that as a cause of the condition. As regards the second possibility, unfortunately no microscopical examination of the brain sectioned and stained for free fat was made; but the case clinically closely resembles three cases of fat embolism of the brain described by Godlee and Williams in April of this year and proved microscopically. The sudden onset of cerebral symptoms without definite localisation, with high temperature but without definitely raised blood tension, within a few hours of an operation for compound fracture of a long bone, render this explanation at least a feasible one.

Perhaps the occurrence of two such rarities as a rupture of the œsophagus and fat embolism in the same subject may be somewhat difficult to accept, but they seem to be the only explanation of a case which was an extremely puzzling and difficult one to explain to a coroner's jury when it occurred.

I have to thank Mr. Roughton, under whose care this patient was at the Royal Free Hospital, for permission to publish this case.

THE LEAGUE OF MERCY.—At the annual meeting of this body, which was held at St. James's Palace under the presidency of Lord Farquhar on Dec. 15th, Sir Henry Burdett, the honorary treasurer, reported that the league would be able to distribute £19,200, the total collection for the year having amounted to £19,385.

FIBROID INDURATION OF THE MEDIASTINUM PROBABLY SYPHILITIC.

BY W. BRANDER, M.D. ABERD.,
MEDICAL OFFICER, SHEFFIELD UNION HOSPITAL;
AND
J. B. H. HOLROYD, M.R.C.S. ENG., L.R.C.P. LOND.,
ASSISTANT MEDICAL OFFICER.

THE following case of extensive fibroid induration of the mediastinum and right lung, with ulceration and sclerosis of the right bronchus, as well as perforation of the pulmonary artery of the same side, is reported chiefly on account of the difficulty in diagnosis and also because it probably belongs to the class of pulmonary syphilis.

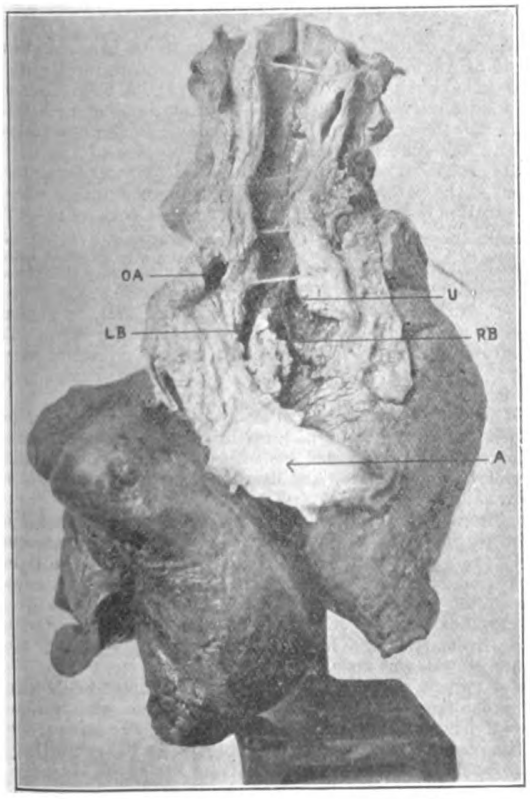
The patient, a man, aged 62, first came under observation on Feb. 10th, 1910, suffering from hæmoptysis and swelling of the right hand.

History.—The family history is unimportant. The patient's habits were temperate. He stated that his own health up to the commencement of the present illness had always been very good. He denied ever having had syphilis. Six months ago he began to suffer from cough and shortness of breath, and three months later had a slight hæmoptysis. He was, however, able to perform light work, and continued doing so until two days before admission in spite of the frequent spitting of small quantities of blood and pain across the front of the chest.

Condition on admission.—On admission the patient was a man of good muscular development. He was cyanosed and had constant dyspnœa. The superficial veins of the chest and neck were very full, especially on the right side; there was also a well-defined bow of dilated venules, roughly following the line of attachment of the diaphragm on both sides. He suffered from a harassing cough, accompanied by a little thick yellow expectoration which was streaked with blood. The pulse was 86, full and bounding, regular, and equal at both sides. The superficial arteries were thickened and slightly calcareous. Respirations 30; temperature 97·4° F.

The thorax was well formed, but the respiratory movements on the right side were impaired. There was absolute dulness on percussion over the right side from apex to base, both in front and behind. In front the dulness extended across the middle of the chest to an inch beyond the mammary line from the level of the third costal cartilage downwards to the sixth rib. The resonance was normal over the rest of the left side, except at the base, where there was slight dulness. Over the whole of the right side tactile vocal fremitus was much diminished; on the left side it was normal. On auscultation the breath sounds over the right lung were very faint and bronchial in character. Over the left lung they were harsh, and the expiration was prolonged. Very fine inspiratory râles were audible at the bases.

The cardiac impulse was palpable in the sixth left intercostal space just outside the mammary line. The heart sounds were distinct, the first normal, the second accentuated; no murmurs were present. The pupils were equal, no tracheal tugging could be obtained, and there were no signs or symptoms suggesting pressure on the recurrent laryngeal nerves. The urine was of specific gravity 1008, slightly alkaline; no albumin was detected.



After being kept in bed for three months, with 30 grains of iodide of potassium three times a day and a restricted diet, he gradually improved, but when allowed up for a little time he had paroxysmal attacks of dyspnœa and slight hæmoptysis. On April 24th, 1910, he coughed up 3 ounces of bright red blood. He remained under treatment until July 15th, 1910, when he was discharged by request; he still had some signs of intra-thoracic pressure. During the five months he was under observation his temperature was never raised above normal. He gained 2 pounds in weight.

Clinical history.—The patient was re-admitted to hospital on Dec. 13th, 1910, on account of frequent hæmoptysis and dropsy, and was obviously much worse than on Feb. 10th, with more definite signs of intra-thoracic pressure. He had orthopnœa, extreme cyanosis, and œdema of the face, neck, upper part of the thorax, and both arms; also much distension of the superficial veins. There was slight œdema of both legs. The right pupil was contracted and the pulse in the right arm was smaller than that in the left.

The right side of the chest in front bulged at the level of the third, fourth, and fifth ribs The movements of the right side of the chest were diminished, but no visible pulsation was noticed. On percussion of both sides of the chest the areas of dulness were similar to those on his first admission, but the auscultatory phenomena differed. There were tracheal breath sounds over the upper part of the sternum, and these were also present over the right side to the middle point of the clavicle. There was bronchial breathing with sonorous accompaniments over the remaining part of the front of the chest and behind over the right side. No breath sounds were audible below the angle of the scapula. The heart sounds could not be heard. The abdomen was rather full, and the hepatic dulness extended to two inches below the costal margin, where its lower border was distinctly palpable. There were no signs of ascites.

During the next month the patient was treated on similar lines to those of the first admission, the result being that the œdema, except that in the right arm, rapidly disappeared, and a week later the heart sounds were heard. He always complained of pain, which frequently radiated down the right arm, and he had a persistent cough with purulent expectoration, accompanied by attacks of hæmoptysis, the quantity varying from 3 to 6 ounces. On Jan. 10th, 1911, when apparently quite comfortable, he had his fatal hæmoptysis, over a quart of blood being lost. There were no tubercle bacilli in the sputum.

Pathological findings.—On palpating the mediastinal contents *in situ* a large mass was felt above and in front of

Posterior aspect of lungs and trachea. LB, Left bronchus. RB, Right bronchus. U, Ulceration into right bronchus. A, Aorta. O A, Opening made into aorta.

the roots of the lungs, and on the right side it was found to be firmly adherent to the spine. The right pleural cavity contained about 8 ounces of blood-stained fluid. The whole of the thoracic contents were removed intact, and it was then discovered that all the structures in the posterior mediastinum were involved in this dense fibrous mass. After careful dissection—which included the opening of the trachea and bronchi from behind—the following conditions were found (see figure).

Immediately below the origin of the right bronchus there was a small opening large enough to admit a penholder, which was ulcerated, as well as showing much induration. The opening communicated with a cavity in the uppermost lobe of the lung, which was about two inches in diameter. The cavity did not appear to have any definite wall, but presented a shaggy appearance. It contained some blood clot, which on being cleared away revealed a small opening into the main trunk of the right pulmonary artery. Apart from the cavity, the uppermost lobe of the right lung was solid and indurated. On section it had a dull greyish appearance, and there was much thickening of the surrounding pleura, especially behind. There was no bronchiectasy, and the rest of the lungs showed no abnormality beyond emphysema at the margins. The bronchial glands were slightly enlarged.

Sections were made from the dense tissue surrounding the roots of the lungs and the margins of the opening in the bronchus, and were found on microscopical examination to consist of fibrous tissue, while sections from the apex of the right lung and from a part near the cavity showed fibrous overgrowth with excessive pigmentation.

In spite of a negative history, these pathological findings suggest that a gumma existed at or near the right bronchus which gave rise to much fibrous induration and interstitial pneumonia. In the latter excavation had taken place, and the necrotic process produced ulceration of the trunk of the pulmonary artery.

CARCINOMA OF THE BOWEL

COEXISTING WITH BENIGN GROWTHS OF THE FEMALE PELVIC ORGANS.

BY J. S. MANSON, M.B., B.CH. EDIN., D.P.H.,
VISITING SURGEON, WARRINGTON INFIRMARY.

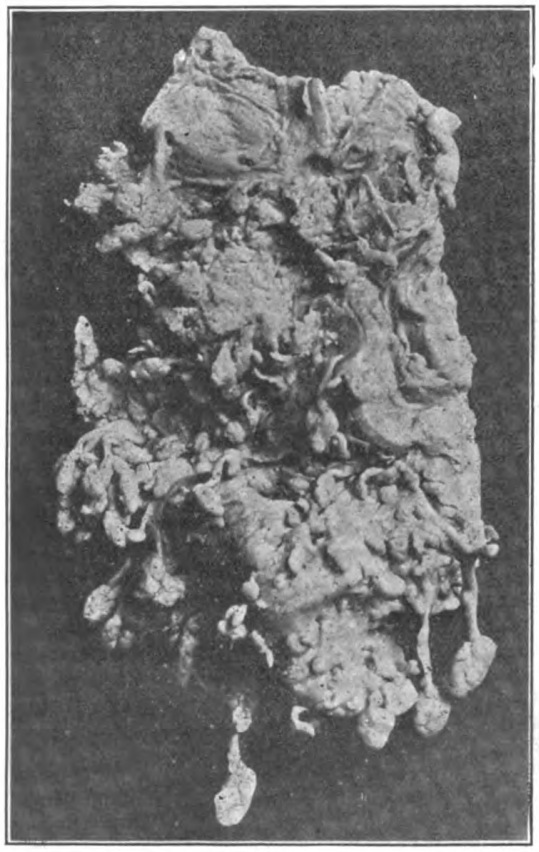
CLINICAL observation and pathological investigation of cases of morbid growths are still of interest, even in these days of their study from the experimental side. The following are the details of two cases which occurred recently in my practice here.

CASE 1.—The patient was a widow aged 39 years. She married when she was 19, and had five children, two of whom are alive. The last child—a boy—was born when she was 30 years old, and she had not been pregnant since. Her husband died five years later. She had typhoid fever when she was 27, but no other illness. There was no history of malignant disease in the family.

During the early part of 1910 she complained of abdominal pains, and on April 11th she passed some blood per rectum. I saw her for the first time on April 14th, and was shown about half a pint of clotted blood, which was said to have come from the bowel. She was very pallid and sallow. The body was well nourished. She complained of pain in the right iliac region. The abdomen was slightly distended. In the right iliac region and lumbar regions there were dulness on percussion and considerable resistance to palpation. Vaginal examination revealed a hard moveable mass in the pouch of Douglas. Rectal examination proved negative. Nothing of the nature of growth or ulceration could be felt by the examining finger. In front the hard moveable mass in the pouch of Douglas could be easily palpated.

A diagnosis of ovarian tumour was made, and it was thought that the intermittent bleeding from the rectum was due to congestion from pressure of the mass on the rectum.

About the latter end of July the patient was sent to the Manchester Royal Infirmary, where Dr. A. Donald removed from the right side a cystic ovarian tumour of about the size of a fœtal head, and from the left side a solid ovarian tumour almost as large. Palpation of the rectum at the time of the operation showed nothing in the nature of growth. Both tumours had very distinct pedicles; they were not adherent and gave no difficulty in removal.



Examination of the tumours proved that the tumour from the right side was an ordinary multilocular ovarian cyst, while the left tumour was an ovarian fibromyoma.

So far the case seemed quite simple, although it was unusual to find double ovarian growths of a different nature. After the operation the patient's health did not improve

much, except that she was free from the oppressive pain of the right side. After a stay of a couple of months in hospital and convalescent home, she returned home in September, when I again attended her. She was then very ill and cachectic-looking, and had passed blood per rectum. The left leg and foot were swollen, and through the now flaccid abdomen a hard nodular mass could be felt in the left iliac fossa. There could be no doubt now but that she was suffering from malignant disease of the sigmoid colon. She died on Oct. 21st.

Necropsy.—On the next day I made a post-mortem examination of the abdominal cavity and removed the sigmoid colon for further examination. The liver was studded with nodular masses of growth of various sizes. I removed one of the nodules for microscopical examination. There were a few enlarged glands in the mesentery, but there was no further evidence of disease in any other part of the bowel or other organs. The stumps of the ovarian pedicles were adherent to the lateral walls of the pelvis and showed no sign of growth.

On slitting up the removed portion of colon a remarkable appearance presented itself. Studded over the whole surface of the mucosa were numerous red polypi, some sessile, some with fragile pedicles, which easily washed off by the stream of water used in cleansing the part. The accompanying illustration shows this appearance very well. The

Reproduction of photograph of columnar-celled carcinoma of sigmoid colon with polypoid growths, from Case 1.

muscular coat was irregularly thickened, and in one part was a large nodule of degenerated and friable material. There was no stricture.

Microscopical examination of the polypi showed them to be composed of columnar-celled acini with very attenuated basement membranes and stroma. Sections of the muscular coat showed groups of columnar cells invading the muscle tissue. Sections from the liver also showed groups of columnar cells invading the liver tissue, although here the growth cells were more of a mixed character.

This case illustrates in one individual the simultaneous development of three, if not four, distinct varieties of morbid growth without any apparent common causal relationship between them.

The multilocular cyst of the right ovary and the fibromyoma of the left ovary were apparently benign tumours. They gave rise to no other symptoms but those due to local pressure. As there is a history of sterility between the ages of 31 and 35 it is possible that these tumours commenced to form about this time, growing steadily awhile, until the left solid tumour fell by its own weight into the pouch of Douglas, causing pressure on the rectum. Long-continued congestion may have been a factor in the production of the numerous innocent-looking polypi.

Cases are quoted where such polypi become in time associated with malignant growth, and Professor Hansemann in his recent atlas on malignant growths calls special attention to this point. Cathcart[1] quotes a case by Dr. H. Handford at great length. While the polypi may be primary or secondary to the carcinoma, no other relationship can be established between it and the ovarian tumours than that of coexistence.

CASE 2.—The patient was an unmarried woman, aged 48. Towards the end of 1910, and during the early part of 1911, she suffered severely from paroxysms of abdominal pain. She had also severe metrorrhagia, which was almost continuous during the early months of 1911. In March, 1911, she was sent as an in-patient to a London hospital, and in April she had supravaginal hysterectomy performed for a simple fibromyoma of the uterus. At the time of the operation several hard nodules like calcified glands were found in Douglas's pouch, and at the back of the right broad ligament. These were thought to be old tuberculous glands. There were no other signs or symptoms of disease at the time of the operation.

After the usual stay in hospital she returned in May to Warrington. I saw her first on June 26th. She was then complaining of severe pains in the abdomen, and chiefly on the right side. These continued off and on in spite of treatment, and she did not put on flesh, as was to be expected after successfully passing through a major operation for a simple growth.

Suspicions of malignant disease began to be aroused about the end of August, when an icteric tinge appeared in the conjunctivæ. About the middle of September Dr. A. T. Wilkinson, of Manchester, was called in consultation, and after a prolonged and thorough examination he came to the conclusion that she was suffering from malignant disease of the liver, probably secondary to a focus in the bowel. Shortly after this I received the pathologist's report from the hospital at which the operation took place. This report ran as follows:—

A simple fibro-myoma of the uterus and a small fibroid of the broad ligament. On one of the tumours mentioned there is attached to its surface a patch of typical columnar-celled carcinoma like that of the rectum. No other signs of any malignant growth found.

Dr. E. H. Shaw, the pathologist to the hospital, on finding the patch of carcinoma, visited the patient in the ward, and specially investigated the case from the point of view of any symptoms of malignant disease and found none present.

The progress of the case was steadily downward, and at no time were there any signs of intestinal obstruction excepting the occasional paroxysms of severe pain. The patient gradually became more jaundiced and emaciated, and died on Nov. 23rd.

No internal post-mortem examination was permitted, but careful palpation of the abdomen after death revealed more clearly than during life a hard nodular mass in the right lumbar region, and in addition the liver edge could be felt as hard and nodular. Like Case 1, this patient also died from carcinoma of the lower bowel, with secondary growths in the liver, although in this case the exact site of the primary growth was not determined.

These two cases seem to be of special interest in showing that carcinoma of the lower bowel may coexist with various forms of benign growths of the female pelvic organs, and that the prominence of the latter may mask almost entirely the graver disease which gives so little sign of its presence. In both of these cases the presence of malignant disease of the bowel was suspected and looked for while the patient was in hospital, but the symptoms and physical signs were wanting, and no further operative procedure seemed justifiable.

Nothing could be more disappointing to all concerned than this complication, for the surgery of the benign tumours of the female pelvic organs is usually so satisfactory that it is cheerfully recommended and readily undertaken.

I must thank Dr. G. F. Blacker for his suggestions and information in Case 2.

Warrington.

[1] Essential Similarity between Innocent and Malignant Growths.

A TYPE OF NERVOUS VOMITING IN CHILDHOOD.

BY ERIC BELLINGHAM SMITH, M.D. LOND., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN, QUEEN'S HOSPITAL FOR CHILDREN.

THIS paper proposes to deal shortly with a type of nervous vomiting occurring in children about the age of the second dentition. The condition in question has received but little attention in modern text-books, is not uncommonly seen in the out-patient department of a children's hospital, and is not infrequently overlooked.

Inquiry into the time and nature of this vomiting reveals the fact that it is not periodic, but is of a persistent character; and that often, when untreated or when treated unsuccessfully, it may continue for many weeks. It occurs during a meal, or more usually directly the meal is finished, and is of frequent, if not of daily, occurrence. Further inquiry shows that it is painless and effortless, and that it is neither preceded by any organic disturbance, nor followed by any after ill-effects. No diet, no ordinary gastric sedatives, appear to influence it. But with all this—and this is a feature to which I would draw special attention—the child seems neither to lose weight nor to suffer in any respect an alteration in its general appearance of well-being.

This nervous phenomenon, however, while apparently inducing little or no change in the general health of the child, creates a great deal of distress in the minds of the relatives concerned, and generally reflects very little credit on the therapeutics of the practitioner who fails to recognise its real nature. On the other hand, when diagnosed, a very simple remedy suffices in most instances to effect a cure.

Observation of both parent and child is often of value. The mother is frequently of a neurotic temperament, one who suffers from headaches and backaches, and has little or no control over her own offspring. The child, sometimes thin, sometimes well nourished, is frequently of a reserved and introspective nature. Occasionally, and I think much less commonly, the child is emotional and highly timid, one who cries on being undressed, or struggles and shrinks from any examination that involves a stethoscope or spatula.

A review of the histories of these cases generally discloses the presence of other functional nervous disorders, such as enuresis, migraine, and habit-spasm; or in some cases a rheumatic diathesis.

The further description of this complaint is, perhaps, best served by reference to some seven cases which have come under my notice during the past two years. Of these I intend to deal fully with the first two, which were under observation for a considerable period, and which to a marked degree exhibit all the symptoms and associations that have been described above.

Notes of Cases.

CASE 1.—The patient was a boy, aged 8, who for three months previous to being brought to hospital had suffered from constant sickness. Advice had been sought in many directions, but without success. According to the mother the vomiting was of daily occurrence, and took place almost immediately after a meal, and involved, if not all the food taken, at all events a great part of it. Further, the vomiting was not associated with any pain, and was apparently effortless in character. Previously to the onset of the sickness the boy had been subject to periodic attacks of severe headache, the nature of which suggested migraine. The child was also said to be very nervous, a fact which was borne out on examination.

The most careful scrutiny, however, failed to elicit any evidence of disease beyond a history of slight constipation, and the presence of some arrested dental caries. But one feature in this case was very noticeable; despite the three months history of repeated emesis the boy presented a picture of perfect health and more than average nutrition.

Treatment was commenced by a visit to the dental and ophthalmic departments of the hospital, and what little dental caries was present was treated, while the ophthalmic report showed him to be free from any error of refraction or any gross fundal change.

A careful revision was then made in the diet, and for some weeks a variety of anti-dyspeptic remedies and gastric sedatives were tried, but without any success. At this point the similarity of the condition to another nervous intestinal trouble—lienteric diarrhœa—suggested the use of two drugs which have proved of undoubted value in the latter condition—namely, arsenic and opium. A dose of liq. arsenicalis (m i) and tinct. opii (m ii) was therefore prescribed to be taken before each meal. The effect was almost immediate, the vomiting ceasing after the first two or three doses. At the end of a month the mother ceased her attendance, with the result that the vomiting recurred. A few days later treatment was again instituted and again proved successful, this time permanently. Five weeks later, however, as if to confirm the diagnosis, enuresis commenced, but this was easily controlled by the administration of belladonna. A year later both vomiting and enuresis returned, and were again successfully combated by the above drugs.

CASE 2.—The patient was a girl, aged 11 years, who was described by her aunt as always languid, nervous, and subject to headaches. For some weeks she had been fidgety and making faces, and more recently had been very sick after her meals. The vomiting was of the same effortless, painless variety as in the above case, occurring directly after the ingestion of food, and apparently unassociated with any alteration in the child's nutrition. On examination she was a tall, thin, overgrown girl, who flushed and fidgeted when spoken to; and who, when not under observation, exhibited marked signs of habit-spasm. As before, a thorough examination failed to detect any symptoms of organic disease.

The same steps were taken as in the previous case to eliminate any possible underlying gastro-intestinal disturbance or any peripheral or external causes which might be affecting the child's general health, but with no success as regards the vomiting. A change of scene was arranged, which was beneficial for a short time, but with no permanent result. Finally, with the experience of the former case in mind, resort was had to the same combination of drugs which had been so successful before—a step which was again attended by the same happy result. The medicine was continued for a few weeks and then stopped altogether. There was no immediate recurrence of symptoms.

In the course of the next year two trifling attacks of sickness occurred during periods of ill-health due to other causes; these were easily controlled by a repetition of the old formula.

CASE 3.—The patient was a girl aged 10 years, who also was described as being very nervous. A year previously she suffered from an attack of chorea, while more recently she had exhibited all the symptoms of the type of vomiting under discussion. As in the previous cases, the sickness ceased rapidly under treatment. Three weeks after all vomiting had stopped the child was seized with an attack of acute rheumatism.

CASE 4.—The patient was a girl aged 6 years, who, directly her midday meal was finished, would immediately leave the table, go to the scullery, and be sick. Here, again, the vomiting was a simple easy regurgitation of food taken, and was unassociated with any pain or discomfort. This case was lost sight of after a fortnight, at the end of which time all vomiting had ceased as the result of treatment.

CASE 5.—The patient was a girl aged 9 years, in whose case the vomiting occurred, not at the end of a meal, but during the course of it, so that she had frequently to leave the table in a great hurry. She was a fat, healthy looking child, said to be nervous, cried when spoken to, and was easily upset by schoolwork. The mother was a thin neurotic woman, with an obvious lack of control over her child. A brother and a sister of this girl both exhibited definite stigmata of a nervous inheritance. It is of interest to note that this child never vomited when she partook of meals at school. In this case a reptition of the treatment employed in previous cases was again successful.

CASE 6.—The patient was a boy, aged 10 years, who had been sent to hospital as a case of chronic appendicitis. This boy shrieked and struggled when he was undressed like a child of 2 years old, and complained of pain everywhere he was touched. On examination there was no evidence of any intra-abdominal disease, and a few days of judicious hospital control, and the administration of arsenic and opium as before, sufficed to cure his persistent vomiting.

CASE 7.—The patient was a girl aged 8 years, described as very nervous. In her mother's words, "she gets up after almost every meal and goes outside and is sick, she never has any pain, and never appears to experience any discomfort after the sickness is over." As an infant this child suffered from severe rickets, and neither walked nor talked till after 2 years old. At the date of examination, with the exception of some defect in her speech as regards certain consonants, she presented no evidence of any functional or organic disease. The only other child in the family was a somnambulist. Treatment was conducted along the same lines as before, and, as in previous cases, a successful result was not obtained until the administration of arsenic and opium was set on foot. Relief was then rapid and permanent.

Remarks.

It will be noticed in all these cases that every effort was made, in the first instance, to eliminate any factor, local or peripheral, that might possibly give rise to vomiting. The evidence in favour of the condition being a purely functional one is—1. The underlying current of nervous instability or nervous inheritance present in every case. 2. The fact that the vomiting in at least the first two cases was preceded, accompanied, or followed by other functional nervous disorders—e.g., migraine and enuresis in the first case, and habit spasm in the second, while the third case was a rheumatic subject, and the seventh case suffered from that common precursor of functional nervous disorders—namely, rickets. The effects of unsuitable environment are well shown in the fifth case, where the child, though said to constantly vomit at home, never did so when fed at school.

Pathology.—The explanation of the causation of this disease seems sufficiently simple. The vomiting in question appears to be due to some inherited or acquired hyper-excitability of the nervous mechanism of the stomach, which fails to allow of the retention of any considerable quantity of food. This complaint is thus comparable in many respects to the hyper-excitability of the bladder in enuresis, and to that increase of nervous irritability of the intestine which gives rise to lienteric diarrhœa. Moreover, as we have seen above, the same drugs which are of value in the latter complaint are of inestimable use in neurotic vomiting. The retention of fair nutrition and good health can only be explained on the assumption that the vomiting is either never complete, or never, as a rule, takes place after every meal.

Diagnosis.—If the principal features of this disease be

borne in mind—namely, painless, effortless vomiting, occurring directly after meals, without alteration in the general health, and having its origin in children of nervous habits or inheritance—there should be little difficulty in making a correct diagnosis. The child with chronic intestinal dyspepsia, or mucous disease, generally wastes, has epigastric pains and other symptoms, but rarely vomits. In cerebral tumour there may be effortless, painless vomiting, but it has no direct relation to meals; headache is usually persistent and severe, and later there will be optic neuritis, and perhaps localising symptoms.

The regular and daily nature of the sickness easily distinguishes it from that large group of cases of cyclical or periodic vomiting which are dependent on sundry auto-intoxications or are manifestations in the child of migraine. Vomiting due to any intra-abdominal lesion should be easily recognised by a careful examination.

Treatment.—This resolves itself into an elimination of all causes that may aggravate the underlying nervous instability. Removal from unsuitable home surroundings and the application of a little firm moral control will often effect a cure. In obstinate cases the same treatment as is applicable to lienteric diarrhœa—namely, small doses of arsenic and opium given just before meals—has in the author's experience always proved immediately efficacious.

Weymouth-street, W.

TWO CASES OF ECTOPIC GESTATION WITH PRIMARY RUPTURE INTO THE ABDOMINAL CAVITY.

BY W. MANSON FERGUSSON, M.D. ABERD., L.M. ROTUNDA,
ASSISTANT SURGEON, CHALMERS HOSPITAL, BANFF.

THE following two cases occurred within six weeks of one another, are typical examples of their kind, and present certain interesting features.

CASE 1.—The patient, married, aged 25 years, was admitted into Chalmers Hospital at noon on July 22nd, 1911. She was the mother of two children, aged 4 and 2. There had been no miscarriages, and her periods had been very regular up to the end of the previous April.

About 7 P.M. on the day before admission the patient had been seized with pain all down the middle line of her abdomen and severe vomiting. She went to bed but did not sleep, and getting up to pass urine at 2.30 A.M. fainted. At 7 A.M. she got up and started to make her husband's breakfast, managed to light the fire and partly cook the porridge, and again fainted. At 10.30 A.M. she was feeling very ill and at last sent for Dr. J. C. Galloway, who diagnosed extra-uterine pregnancy and called in consultation Dr. J. Anderson, who agreed with the diagnosis and advised immediate removal to hospital for operation.

Dr. Anderson met me at the hospital and gave me the following particulars about the case. The abdomen was remarkably soft, and extensive dulness could be made out on both flanks, the dulness being slowly moveable. There was pain on deep palpation over the right side. Vaginal examination: The cervix was somewhat soft and patulous but closed, with the canal pointing slightly to the right. The uterus could be easily palpated bimanually and seemed very little enlarged, but was carried bodily towards the left side for about two inches at the fundus. To the right of the uterus there could be felt a soft boggy swelling of about the size of a small lemon, and there was also a boggy feeling in Douglas's pouch. Immediately prior to operation her temperature was 96° F. and her pulse 150; she was absolutely blanched, and her abdomen was dull on percussion all over.

Dr. Chance put the patient under with chloroform and then changed to ether by the open method, and a very satisfactory anæsthesia was maintained.

On going through the abdominal wall there was no bleeding at all, and when the peritoneum was opened there was a rush of very dark blood. The peritoneal cavity was full of this and large clots of the size of one's fist. On bringing up the uterus I found a rent in its right side beginning on the fundus and extending downwards for 1½ in. to 2 in. At the lower end of this rent I could see the cross section of the uterine artery, which was not bleeding at all. On exploring the rent I found a cavity of about the size of a pigeon's egg with no appreciable opening into the uterus. I pushed my way through into the uterus and scraped out the false decidua with a curette and opened up the cervix. I then trimmed up the edges of the rent and closed it by two layers of iodine catgut, ligaturing the artery referred to and its accompanying veins. The right ovary was twice the normal size and cystic, so I removed it along with its tube.

The abdomen was irrigated with saline solution, a pint or two of which was left in, and the abdominal wall was sutured in the ordinary way. When suturing the peritoneum and also the rectus I was struck with the extreme friability of those tissues, the slightest traction on them producing extensive tears. I had never seen anything like it, and remarked upon it to Dr. Anderson, who was assisting me, and he said that he had seen a similar condition in a case of hæmorrhagic pancreatitis.

On the completion of the operation the patient was given a rectal saline containing 1 oz. of brandy and 1 dr. of liq. adrenalin. The foot of her bed was raised and rectal salines, omitting the brandy, were continued for 24 hours. She was then gradually moved up into Fowler's position, and then there commenced a fairly abundant tarry-looking discharge per vaginam, which persisted for a few days. Low pressure douches of biniodide were given for a few days. The patient made an uninterrupted recovery. So well was she that on the ninth day after operation she got up out of bed when her nurse was out of the room, and walked to the window to see what was passing along the street.

This interstitial form of ectopic gestation is generally recognised to be the most fatal if rupture into the abdominal cavity should occur, owing to the large vessels which may be involved. Jellett refers to 26 cases, collected by Hecker, of this variety, all of which proved fatal.[1] Munro Kerr gives an account of a case of his own which ruptured and the patient almost died, but rallied and was operated upon some time afterwards successfully.[2]

Since I did the case I have often wondered whether the uterus will give way where it was torn should the patient become pregnant again, and also if I should have sterilised her at the time, seeing she had such a narrow escape. I had no knowledge of any other case except the one given by Munro Kerr, and in it he had to do hysterectomy. I did not think it necessary to do hysterectomy, especially in my patient's collapsed condition, and I resolved not to sterilise her at the time, but to wait until I had an opportunity of discussing the case with others.

If one were quite sure that a scar in this situation were as strong as the Cæsarean section scar, then there would be no question of sterilising such a case as mine. I consulted several gynæcologists about the case and they were all of the opinion that I would not have been justified in sterilising the patient at the time, or even in advising that procedure subsequently. I must say I am rather inclined to the opposite view, but perhaps some of the readers of THE LANCET may have had similar cases which I have not come across in looking for references to this variety of ectopic gestation.

CASE 2.—The patient, married, aged 29 years, sent for me on August 29th, 1911, and gave the following history. On August 11th she had not menstruated for seven weeks, and on that date she passed a "fleshy lump," accompanied by a certain amount of blood. She was quite well until the 25th, and on that day was seized with pain in the lower part of the abdomen and severe vomiting. This attack lasted only a few hours, and she felt fairly well until the 26th, when what she thought a period started, along with very severe pain in the left iliac region and vomiting. She kept her bed and applied hot fomentations. The pain and vomiting ceased, but the vaginal discharge continued.

When I saw her for the first time at about 1 P.M. on August 29th she was feeling quite well, but had a little tenderness in the left iliac region, and on vaginal examination a distinct swelling was palpable immediately to the left of the uterus. I suspected that it was a case of tubal pregnancy, told her husband of my suspicions, and advised a consultation the following day. About three hours after my visit she was again seized with pain and vomiting and fainted. I was sent for, and on my arrival found her very collapsed, her pulse running at 130 and her temperature would not rise above 96° F. There was dulness on percussion

[2] Munro Kerr's Operative Midwifery, pp. 542-3.

all over the lower half of the abdomen and up to the left flank.

As it was a small house in the country I had her taken into hospital, although it was five miles away. She had no radial pulse on arrival at hospital about 10 P.M., but was put on the table immediately and given a rectal saline with brandy and adrenalin. On opening the abdomen I found it almost full of blood and blood clot. The left tube was distended to the size of a hen's egg, and had ruptured on its posterior aspect. The left tube was removed and the abdomen sutured up, after irrigating with saline solution, a quantity of which was left in. Rectal salines containing ½ oz. of brandy and 1 dr. of liq. adrenalin were given four-hourly for 48 hours, and the patient gradually rallied and made an uninterrupted recovery.

Case 2 is undoubtedly a very typical case of ectopic gestation ending in primary rupture into the abdominal cavity, and the only rather rare feature is that the attacks of abdominal pain were accompanied by severe vomiting. The reason why I have reported it is that I consider it a very good example of the harm which may be done by a vaginal examination if the least force is used to determine the pelvic condition. I was extremely careful in my examination, but I am convinced that my examination had something to do with the final rupture.

Banff.

SEVERAL ATTACKS OF APPENDICITIS IN AN APPENDIX SITUATED IN THE SAC OF A SCROTAL HERNIA; OPERATION; RECOVERY.

BY C. H. JAMES, F.R.C.S. ENG.,
LIEUTENANT-COLONEL, I.M.S.

THE following case presents several unusual peculiarities which make its publication desirable. The fact that the cæcum with the vermiform appendix has frequently been found during operation in a scrotal hernia, especially of the right side, is too well known to need more than a passing mention in these notes, but the fact that such displacements of the appendix are liable to inflammation and even suppuration is not generally known or, at any rate, appreciated. The early age of the patient and the fact that the operation in the present case was a long and tedious one add to its interesting features.

The patient, the son of a labourer, was admitted into hospital complaining of excessive pain, tenderness, and swelling of the scrotum. The boy, whose age was stated to be seven years, but who from his size looked less, was very ill. He had high fever (102° F.), the pulse 120, and was evidently in great distress. The history given by the father was that when the child was 2 months old a swelling was noticed in the right inguinal region, but that it was easily reducible by pressing with the fingers, and therefore nothing in the way of treatment was done for it. Indeed, there was no inconvenience at all till about a year ago, when the child began to have attacks of pain in the scrotum, which increased greatly in size. In these attacks he had vomiting and diarrhœa, which lasted three or four days, and then the symptoms gradually ceased and the swelling of the scrotum subsided. There had been three such attacks during the year, after each of which the patient recovered more or less completely, but it was noticed that the hernia could not be reduced as had been the case formerly. In fact, it had become irreducible. The last attack was the worst, and for this the boy was brought to the Rajindar Hospital, Patiala.

On examination the right side of the scrotum was found to be swollen to the size of a man's fist. The skin was red and shiny and acutely tender, and fluctuation could easily be detected. The lower abdomen was rigid and the boy complained bitterly of griping pains which came on at intervals and then passed off. There had been vomiting before admission but none afterwards. The bowels acted after admission, and therefore there seemed prospects of spontaneous relief. The case was put down by the house surgeon for operation next morning, but during the night the abscess in the scrotum burst of itself and a large quantity of pus escaped. The temperature and pulse quickly came down to normal, and the little patient seemed in every way convalescent. The scrotum, however, did not diminish much in size and the tympanitic resonance of inflated intestine within it could still be easily elicited on percussion. There was a small sinus at the upper part of the scrotum near the middle line—the result of the abscess—which showed no signs of healing.

After the patient has been in hospital a month and had sufficiently regained his strength I decided to operate. On May 1st I opened up the scrotum by making an oblique incision commencing over the situation of the internal inguinal ring and extending to the bottom of the scrotum. The sac was filled with large intestine which was everywhere firmly adherent to the walls and the separation of which was a matter of patient and tedious dissection. The vermiform appendix soon came in sight. It was about three inches in length and distinctly thickened and rigid. It ran for about an inch from the lower end of the cæcum to the skin opening, where its lumen communicated with the external sinus already mentioned. At this point it was sharply bent on itself and the remaining two inches of its distal portion lay imbedded in adhesions. The whole appendix was dissected out and the opening in the cæcum closed in the usual way. The remaining portion of protruding intestines was next freed from its attachments to the sac and returned into the abdominal cavity. The neck of the hernia was large, easily admitting three fingers. A radical cure was performed by tying the neck and cutting away the rest of the sac and suturing together the sides of the inguinal canal with buried sutures. The testicle lay in a separate sac—the tunica vaginalis—and was not disturbed.

The operation lasted over an hour. The patient made an uninterrupted recovery and left hospital on May 24th, 1911.

It will be observed that the boy had three distinct and typical attacks of appendicitis, the last of which resulted in abscess of the scrotum which opened externally and formed a permanent sinus. The track of the sinus was the lumen of the proximal portion of the appendix. In spite of this no fæcal matter ever escaped by this route. The case seems an easy one to diagnose when viewed by the light of after events, but was certainly very puzzling when first admitted to hospital. The history of previous attacks was only elicited with difficulty from a stupid and illiterate father after the operation had been performed. It is also interesting to note that although the hernia was noticed soon after birth it was not of the congenital but of the acquired variety, that is to say, the tunica vaginalis was not continuous with the hernial sac, but formed a separate compartment.

SURGICAL SECTION.

Intestinal Obstruction following Ovariotomy.—Radical Cure of Hernia in Infants.—Treatment of Clawfoot.

A MEETING of this section was held on Dec. 12th, with MR. CLINTON T. DENT, the President, in the chair.

The PRESIDENT read a paper on a case of Intestinal Obstruction following an operation for Ovariotomy performed 45 years previously. In the course of his remarks he said that a surgical point of the greatest interest was the formation of adhesions. All the pregnancies of the patient had been quite normal. There had never been any perimetritis or parametritis, nor had there been any illness that might have led to the formation of adhesions. It might be taken as certain that there was no malignant disease of the large intestine, although the possibility of that had been suspected. On the other hand, there was a history of trouble following the ovariotomy, and of suppuration about the pedicle, which was fixed to the abdominal wound. His own view was that the adhesions commenced at that time, and that they had persisted throughout the patient's life, though they had never given rise to any serious trouble. Adhesions of other serous membranes, such as the pleura, might undoubtedly persist for an indefinite length of time without ever being suspected. In the case of the pleura they were less likely to undergo any material changes, but the free movements of the intestines and the alterations in the disposition

of the viscera resulting from pregnancies would profoundly modify peritoneal adhesions. Some of them might disappear; others might become tougher until adjacent coils of intestine became firmly welded together or to the abdominal wall or other viscera; or the adhesions might become stretched, avascular, tough, and string-like according to the local conditions, and those changes might take place gradually and extend over a great number of years, never being suspected, until ultimately they led, perhaps suddenly, to grave symptoms. The patient had been troubled with constipation for a good many years, and that condition might have been partly or even wholly dependent on the presence of the adhesions; on the other hand, the constipation might have been quite independent of them. All pathologists would, he thought, agree that extensive intestinal adhesions were frequently found post mortem when there had been no symptoms during life to indicate their presence, and where there was no obvious post-mortem explanation of their original formation. They were certainly found, and not infrequently, where abdominal operations had been performed, although to all appearance the patient made an absolutely uninterrupted recovery without any complication at all. When a pedicle in an ordinary case of ovariotomy had been ligatured with silk the ligatures might come away years after the operation, and in such cases it was highly probable that some adhesions had formed. They might have disappeared again, but that was not likely, and he thought that after almost any abdominal operation, however uncomplicated and apparently complete recovery was in every respect, some intestinal, or at any rate omental, adhesions were usually present. Once present, they might persist, for the mere fact that adhesions were present was likely to lead to formation of further adhesions, so that although some might disappear others might take their place. Hysterectomy, particularly abdominal hysterectomy, was especially liable to be followed by the formation of extensive adhesions.

Mr. THOMAS H. KELLOCK read a paper on the Radical Cure of Hernia in Infants and Young Children. He said there was probably no operation in surgery of children that had come more into practice during the last few years than that for the cure of inguinal hernia, and rightly so, he thought; for he held very strongly the view that all of those were congenital in origin, as far, at any rate, as the sac was concerned, and that the only "acquired" factor was the protrusion of some viscus into an already existing sac, and he thought, too, that the removal of that congenital deformity was the proper course, and the only course, if a cure in the proper sense of the word was to be brought about. One heard of, and apparently saw, cases that were said to have recovered spontaneously or been cured by the application of a truss, yet he believed in those cases an unoccupied sac remained only waiting for some unaccustomed internal pressure to bring about what one so frequently saw, the sudden, almost painless, occurrence of an inguinal hernia of some considerable size in a young adult How operations for hernia had increased in number was shown by the statistics of the Hospital for Sick Children, Great Ormond-street, for he found that whilst in the year 1898 18 operations for that condition were performed, in 1910 the number had risen to 369. He thought an operation could, and should, be done at an early age; as to the nature of the operation that gave the best results there would seem to be some difference of opinion; for his own part, for several years past he had reduced it to the very simplest form that he thought would answer the purpose. The test of the efficiency of any operation for that condition could only be made by investigating the results some years subsequently, and in order to see what those results had been in some of his own cases he recently, with the help of his late house surgeon, Mr. C. Bryan, made an investigation into a number of cases which proved to be of considerable interest. From the hospital registers they took 75 cases which had been operated on from two to four years ago; they did not go further back because it was only about four years ago that he began to perform the simple operation which he should presently describe. To 50 of the cases they sent postcards asking the mothers to reply on them as to whether there had been any return of the rupture; whilst to 25 who lived within reasonable distance letters were sent asking them to come and be seen. To the 50 inquiries they had received 28 replies; three of the children had died since the operation, two from pneumonia and one from peritonitis 14 months after the operation; one had left the country. In each case the statement was made that up to the time of death or emigration there had been no return of the hernia. One mother stated that there was a bulging when the child coughed. (This patient was sent for and seen subsequently; he had some weakness of the abdominal muscles on both sides above and outside the inguinal canals, but there was no sign of any protrusion through the inguinal canal itself.) In all the other cases the reply was that there was no return of the rupture, and on nearly all the postcards there was some expression of gratitude. Of the 25 patients who were asked to come and be seen 14 presented themselves, and in every one of them the cure seemed to be absolutely satisfactory, so that after the lapse of from two to four years one might claim that a satisfactory result had been obtained in all of them. The ages of the patients at the time of operation varied from a few months to 8 years; 5 were under a year old, 18 between 1 and 2 years, 7 between 2 and 3 years, and smaller numbers at the succeeding ages. In 6 cases the condition was bilateral and the operation done on both sides at the same time. Mr. Kellock attached considerable importance to what might be called the preparatory treatment in these cases; when an infant had a hernia of any size that came down easily he had kept him for a few days before the operation in the Trendelenburg position; it was quite easily managed by fastening the feet and legs over a wedge pillow, and it was rather wonderful how rapidly they became accustomed to the position. After a few days the hernia rarely if ever made its appearance, and when it had not been seen for a day or two the operation was done and the child returned to the same position again for another five or six days. As to the operation itself, he generally made a 1-inch incision through the skin at right angles to the direction of the spermatic cord and just above the external abdominal ring. This incision was well away from the genitals, and being on the line of the blood-vessels was accompanied by very little bleeding; then, dividing the coverings of the cord longitudinally, the sac was found, thoroughly isolated, drawn down with a little force, transfixed and ligatured as high up as it could be reached, and the skin wound closed, his aim being to remove the sac, the whole sac, and nothing but the sac.

Mr. ROBERT JONES (Liverpool) demonstrated some points in the treatment of Clawfoot by means of photographs on a screen.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION.

Cystic Degeneration of the Chorion.—Exhibition of Specimens.

A MEETING of this section was held on Dec. 7th, Dr. AMAND ROUTH, the President, being in the chair.

Dr. R. D. MAXWELL communicated a sequel to a case of Cystic Degeneration of the Chorion. The patient, aged 21, had been married six months. Seven weeks before admission to the London Hospital a hydatid mole was removed under chloroform. A month later some more "white stuff" was passed. On admission on Nov. 10th, 1910, Dr. A H. N. Lewers found the uterus considerably enlarged and the os patulous. On Nov. 15th typical cystic material was removed from the uterus after dilatation with Hegar's bougies. Numerous vesicles could be seen with the naked eye. On section there were some large œdematous villi, and in close relation to them were parts of the uterine walls. Numerous large and small capillary spaces were seen in the muscular wall of the uterus, and in these spaces were numerous chorionic epithelial cells. The patient was discharged on Nov. 26th, but was re-admitted on March 7th, 1911, as hæmorrhage recommenced in January, and continued off and on till admission, when she was found to be markedly anæmic. Ten days later the uterine cavity was again explored under anæsthesia, and a small nodule of tissue measuring two-thirds of an inch by one-third of an inch was removed with a curette. On microscopic examination of the nodule removed there were a few dropsical villi, which were covered with many layers of papillary projections of the chorionic epithelium. There were some small portions of the mucosa and muscularis, on the surface of which were masses of chorionic epithelium. The patient's blanched condition suggested the possibility of widespread blood destruction by a latent syncytial metastasis which produced no physical signs.

For five weeks the patient's anæmia was medically treated, and she rapidly improved both in red corpuscles and hæmoglobin percentage. On April 21st the uterus was again explored by Dr. H. Russell Andrews in the absence of Dr. Lewers, and a small portion of tissue, the size of a pea, was removed. This tissue had the appearance of normal endometrium, which was confirmed by the microscope. When last seen on Nov. 20th the patient was very much improved and felt quite well. Dr. Maxwell said the case illustrated the difficulty that often arose before being able to decide as to the advisability or not of removing a uterus in such cases as the present. Were there any histological features whereby they could distinguish the trophoblast persisting in utero as an innocent parasitic growth nourished by the maternal circulation without invasion of the maternal tissues, from trophoblast of the more dangerous and infiltrating type? In the light of the present case he felt bound to conclude that many hysterectomies, though justifiable in the present state of their knowledge, were probably unnecessary.

Dr. EARDLEY L. HOLLAND showed a specimen of Ovarian Pregnancy. The specimen was removed by Dr. John Phillips from a woman, aged 40, who had never borne children, but who had had one miscarriage nine years before the present pregnancy. After a period of six weeks' amenorrhœa she had an attack of severe abdominal pain and uterine hæmorrhage. She was treated by rest in bed, and no operative interference was undertaken. During the next five months, however, she had recurrent attacks of a similar nature, and was sent into hospital, where operation was immediately performed. The specimen consisted of the enlarged right ovary. A complete capsule of stretched ovarian tissue enclosed old blood-clot, in the midst of which was situated the collapsed gestation sac. Owing to the time which had elapsed between the date of death of the ovum and removal of the specimen, finer histological details were lacking. The specimen, therefore, had only an anatomical value, and threw no light on the mode of embedding of the ovum in the ovary or its subsequent development. In a blood-clot which was expressed from a recently ruptured follicle in the opposite ovary a remarkable structure was found, which undoubtedly consisted of plasmoidal trophoblast. It might be hazarded that this represented an ovum fertilised at a later date than that found in the right ovary; if so, the case was a unique one of bilateral ovarian pregnancy.

Mr. H. BECKWITH WHITEHOUSE exhibited a Primary Carcinoma of the Female Urethra. He referred to the little attention that had been given to this disease in the standard works on gynæcology in this country. He had succeeded in collecting 43 undoubted records of this disease, chiefly from the recorded cases of Wassermann, Ehrendorfer, Burckhardt, and Karaki. No case was included to which a microscopical report was not appended. He first referred to a case seen at the General Hospital, Birmingham, in which the patient, aged 59, had suffered severe pain and difficulty in micturition for about four months. When first seen the bladder was distended, and urine was dribbling from the urethra. The urethral orifice was dark purplish red in colour, depressed, and puckered. The urethra and bladder were explored by Kelly's cystoscope. The bladder mucosa was somewhat œdematous, but no nodules were seen. On withdrawing the cystoscope an ulcer half an inch long was seen in the floor of the urethra, readily bleeding and surrounded by much induration. No glands were felt in the inguinal region. The patient's condition was very feeble and did not admit of a radical operation. Microscopical reports of a portion of growth removed proved it to be a rapidly growing squamous-celled epithelioma. The relationship of carcinoma of the urethra to urethral caruncle and again to urethritis was discussed. Mr. Whitehouse divided the cases into vulvo-urethral and urethral. The vulvo-urethral growths were the more common, 32 out of the 43 cases coming under this category. These appeared either (1) as an irregular dark purple papillomatous growth, bleeding on examination, and resembling a polyp; or (2) in the form of an ulcer produced by the breaking down of an ulcer on the floor of the vestibule at the urethral orifice; or (3) as an induration surrounding the urethral orifice, leading to puckering and contraction of the orifice. Urethral growths were much rarer, and only 11 were included in the list. These appeared either (1) in the form of an irregular, elongated ulcer, involving the mucous membrane of the urethral floor, and having a tendency to extend towards the urethral orifice; or (2) as a peri-urethral induration, with ulceration only in the later stages. As regards pathology, the preponderating type of growth was the squamous-celled carcinoma. Adeno-carcinoma was rare, and occurred in 14 of the cases. Where practicable, wide excision of the growth, together with the inguinal glands, should be practised.

The following specimens were also shown:—

Dr. J. P. HEDLEY: Cervix Adherent to the Posterior Vaginal Wall.

Mr. J. D. BARRIS: Solid Malignant Growth of the Ovary.

Dr. H. MACNAUGHTON JONES: (1) Section of Carcinoma of the Vulva; and (2) Cyst growing from Remains of a Resected Ovary.

Dr. WALTER TATE: Extra-uterine Gestation; Death of the Fœtus near Term; Removal of the Entire Sac three months later.

Mr. WHITEHOUSE: Ruptured Four Months' Gestation in the Rudimentary Horn of a Bicornuate Uterus.

MEDICAL SOCIETY OF LONDON.

Some Remarks on 400 Operations involving the Peritoneum.

A MEETING of this society was held on Dec. 11th, Dr. J. MITCHELL BRUCE being in the chair.

Mr. J. D. MALCOLM read a paper on 400 Consecutive Operations in which the peritoneal cavity had been opened. There were 113 of various kinds on the uterus, with 2 deaths; 103 on the ovaries and Fallopian tubes, with 2 deaths; and 184 on the abdominal wall, intestines, kidneys, gall-bladder, &c., with 4 deaths. Special attention was paid to the fatal cases, and the circumstances surrounding them were compared with those of Mr. Malcolm's earliest work, which showed a mortality nearly three and a half times as high as that of the recent cases. The difference was attributed in part to want of experience and to less effective methods, but it was urged that one of the greatest advances in abdominal work was attributable to a better selection of the time for operating. The more judicious use of opium and of purgatives was considered very important and also the administration of fluids during convalescence, but it was urged that fluid might be given in too great quantity when shock was developing. Trendelenburg's position was considered one of the most useful aids in operating, how useful could only be really appreciated by those who had worked without it. Modern methods of attaining asepsis were also important. There were in the series 54 hysterectomies for fibromyoma uteri without a death, and these were compared with 29 operations by the old method in which the serre-nœud was used, when patients were advised to have no operation until the tumours threatened life or seriously interfered with health. In these early cases there were five deaths, all but one of which, and perhaps all, would have had a very good chance of recovering by modern methods and by earlier operations. Hysterectomy by the vaginal route was performed in one case of complete prolapse of the uterus of ten years' duration, and death from suppression of urine followed. It was found after death that both ureters were dilated to a size of almost half an inch in diameter. In regard to Wertheim's operation for cancer of the cervix, it was urged that the full benefits of this improved method could only be obtained if the disease was diagnosed and treated early. It was urged that the operation should not be performed if the mischief was so widespread that the death-rate was high and the duration of life afterwards was short. There were 44 ovariotomies which all recovered, and these were compared with 54 of the first 100 operations performed by Mr. Malcolm. In these there were five deaths, including incomplete and malignant cases. All these fatal cases were already published. Forty cases of removal of the Fallopian tubes, generally with the ovaries, showed two deaths. In the first fatal case the small intestine ruptured four days after the operation without any sign of inflammation around the perforations. This was the only case of the kind Mr. Malcolm had seen. In the other case there was a very acute salpingitis with pools of pus amongst adherent coils of intestine, such as one had often seen after death. The state of shock was profound at the end of the operation, but the patient lived a week, and at the necropsy it was discovered

that the uterus had fallen back and blocked the drainage opening in the vaginal wall. The advantages of obtaining free drainage, if necessary by removing the uterus, were urged. The contrast was pointed out between cases of intestinal adhesion treated by purgatives and a case operated upon recently in which obstruction was complete but no purgative had been given. There were 20 cases of intestinal anastomosis with two deaths, in which treatment had been long delayed. Of seven intestinal resections one died. A fatal case of nephrectomy was recorded. The kidney was atrophied and contained colourless matter and was surrounded by hardened fat, so that it appeared to be very much enlarged. There were 64 cases of appendicitis with two deaths. The advantages of early operation were urged. A case was recorded in which a gangrenous appendix was successfully removed from a girl aged 22 who was dying from pulmonary tuberculosis, and who did die 15 months later. In another acute case the woman was delivered of a full time child the night after the operation, and both mother and child did well. A child, aged 2½, was operated upon when all symptoms had subsided and the appendix was found ruptured, and in another patient all pain ceased within three days of its onset, but a ruptured appendix and a piece of gangrenous bowel a foot long were removed, the patient recovering without complication. Such cases illustrated the advantages of selecting the proper time for operating in appendicitis and other cases.

HARVEIAN SOCIETY OF LONDON.

Some Surgical Cases illustrating the Diagnostic Value of X Rays.—On Chloroformisation of Patients Sitting in the Upright Position.

A MEETING of this society was held on Dec. 7th, Mr. J. ERNEST LANE, the President, being in the chair.

Mr. E. W. ROUGHTON gave a lantern demonstration on Some Surgical Cases illustrating the Diagnostic Value of X Rays. The cases referred to included many examples of fractures in which, for various reasons, satisfactory apposition of the fragments could only be obtained by operative methods such as wiring, screwing, plating, &c. Cases of chronic abscess were detailed in which the situation of the bone lesion on which they depended could be easily detected by the X rays but by no other means. The demonstration also included examples of disease of the accessory nasal sinuses, renal calculi, foreign bodies of various kinds, and secondary sarcoma of lung.

Mr. J. H. CHALDECOTT read a paper on the Chloroformisation of Patients Sitting in the Upright Position. He said that there was a belief that the administration of chloroform to patients in any but the recumbent position was dangerous; few anæsthetists preferred to employ the upright position. For six years he had administered chloroform to patients of all types and ages sitting bolt upright, and was convinced that this position was for certain operations the most convenient to the surgeon and anæsthetist and of less risk to the patient. The method was useful in nasal and naso-pharyngeal operations. Its success depended on the following points: 1. The patient must be properly prepared to avoid unnecessarily deep anæsthesia. 2. The chair should be a dining-room or kitchen chair with a low back, the patient's feet being supported on a high stool. An arm-chair, and especially an easy chair, was unsuitable. The anæsthetist stood immediately behind the chair and during induction supported the patient's head on his chest. When ready for operation he passed his left arm round the patient's neck, thus controlling the position of the head and holding the mouth-tube of the Junker in the left hand and being able to feel swallowing movements and variation of pulse in the vessels of the neck. The right hand was free to work the bellows or sponge out the mouth. A dental prop should be inserted between the teeth before anæsthesia. To avoid struggling anæsthesia should be induced rapidly with gas and ether or ethyl chloride and ether. When the patient was flaccid chloroform was given on a mask till quiet anæsthesia was established, a naso-pharyngeal sponge being inserted at this stage if required. The administration was then continued through the mouth-tube of the Junker. Comparing anæsthesia in the recumbent and upright positions the questions were: (1) Which was the safer for the patient? (2) Was there difference in the after-effects? (3) Which was the most convenient for the operator? 1. In his opinion for nose and throat operations under chloroform the upright position was the safer. In 1400 administrations he had found the patients were of a better colour, respiration was quieter, and grave symptoms were rare. The alleged danger of syncope did not occur even in subjects of chronic asthma or of cardiac dilatation or goitre because breathing was easier when sitting up than when lying down; mucus, &c., did not pass into the larynx. Tongue forceps were rarely needed. A sponge in the naso-pharynx obviated the risk of blood getting into the larynx. 2. There was less vomiting when this position was used. 3. In the sitting position the surgeon directly faced his work and operated in the position in which he was accustomed to examine the part operated on. Operations could be performed in about half the time required in the recumbent position from the greater ease and the absence of interruptions from coughing. The method was suitable for all nasal and naso-pharyngeal operations requiring continuous anæsthesia, for protracted dental work, and for endoscopy.

LIVERPOOL MEDICAL INSTITUTION.

Exhibition of Cases.—The Value of Pneumococcal Vaccine in the Treatment of Acute Lobar Pneumonia.

A MEETING of this society was held on Dec. 7th, Dr. T. R. BRADSHAW, the President, being in the chair.

The first part of the evening was devoted to the exhibition of clinical cases.

Dr. R. J. M. BUCHANAN showed several cases of Acute Rheumatic Fever, with Polyarthrits, Endo- and Pericarditis, treated and cured by vaccine. One patient had been in full work as a coal-trimmer for ten months after recovering from severe rheumatism and pericarditis. He also showed a case of Splenomegaly with Dwarfism in a girl aged 19, and a case of Tropho-œdema of the Leg in a girl.

Dr. NATHAN RAW read a paper on the Value of Pneumococcal Vaccine in the Treatment of Acute Lobar Pneumonia and other Pneumococcal Infections. His observations were based on 183 cases. The ordinary treatment was supplemented by the use of vaccines. Dr. Raw said that there was an immediate effect in lowering the temperature and the pulse-rate; this effect was temporary. He thought that the complications were less frequent when treated in this way. Neither the mortality nor the duration of the disease had been reduced.—The PRESIDENT did not consider that the use of vaccines in pneumonia was attended by better results than the ordinary treatment. The mortality in 131 cases treated by him was 6·87, a rate almost identical with that found by Dr. A. T. H. Waters some years ago.—Dr. HUBERT ARMSTRONG said that he had found better results in chronic cases than in acute when children were the patients. One case he had treated with doses of 5 and 10 millions every other day; this child developed an empyema and was discharged cured in three months. Ten days later the child returned with pneumonia of the other lung.

The following cases were shown:—

Mr. HUGH E. JONES: 1. A case of Blennorrhœa of both Lacrymal Sacs, Myopia, and Immature Cataract, in which both cataracts had been extracted after preliminary extirpation of both lacrymal sacs, with resulting vision 6/6 and 6/9 respectively. 2. A case of Rodent Ulcer, involving the frontal sinus, ethmoidal cells, and antrum. Attempted radical operation was followed by recurrence in the deep part of the cavity. Carbon-dioxide snow had proved of very little use. 3. A case of Glioma of both Eyeballs. The parents had refused to allow removal of the eyeballs for 18 months and then consented. Four months after enucleation recurrence occurred in one socket, and extensive growths in the neck.

Dr. EDGAR STEVENSON showed a boy, aged 10, from whose Right Orbit he had removed a piece of wood 3 inches long, the pointed end of a home-made arrow. The foreign body had passed through the sphenoidal fissure, and its point must have just crossed the inner end of the petrous bone. The total ophthalmoplegia was passing away, but the eye was blind from optic atrophy.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Dec. 8th, Dr. A. Freeland Fergus, the President, being in the chair.—Mr. W. Ernest Miles (London), in opening a discussion on the Treatment of Carcinoma of the Rectum, said that carcinomatous growths of the rectum differed widely in malignancy, the somewhat rare papilliferous forms seldom recurring, the typical adenoma-carcinoma recurring in 90 per cent. of the cases, and the colloid cancer always recurring. The spread of a cancerous tumour of the rectum was both intramural and extramural; also visible and invisible. The visible intramural spread could be recognised as a direct permeation of the coats of the bowel in the vicinity of the oldest portion of the growth, appearing in some instances as a pearly white infiltration of the submucous coats. The invisible intramural spread could in most cases be demonstrated by the muci-carmine test to extend for several inches in the submucous tissue both above and below the growth. The extramural spread, both visible and invisible, took place in three distinct lymphatic areas—viz., the zone of downward spread, including the peri-anal skin, ischio-rectal fat, and external sphincter muscle; the zone of lateral spread, including the levatores ani muscles, base of bladder, prostate gland or posterior vaginal wall, cervix uteri and base of broad ligament, and associated lymph nodes; and the zone of upward spread, including peritoneum of pelvic floor, pelvic meso-colon, and para-colic and other lymph-nodes. Cases were cited in which spread had taken place extensively within these areas though the growth in the rectum was small and freely moveable. Operations carried out from the perineum, such as Kraske's, Bardenheuer's, and Hochenegg's, could eradicate the tissues composing the zones of lateral and downward spread, but were quite inadequate to reach the tissues of the zone of upward spread. This was illustrated by Mr. Miles's statistics of recurrences in 55 out of 58 cases in which he had performed perineal operations. Resection of the diseased segment with end-to-end anastomosis, whether performed from the perineum or from the abdomen, had failed to prevent recurrence, as had also the so-called abdomino-anal operation, in which the proximal end of the divided colon was brought down to the anus. A radical abdomino-perineal operation, as described by Mr. Miles,[1] was therefore necessary, and should not be reserved for advanced cases, but should be done in as early cases as possible. Mr. Miles's statistics of this operation, performed in 42 cases, showed an operation mortality of 40 per cent, which was markedly influenced by the age of the patients; for while all the 8 cases over the age of 60 died, only 9 of the 34 cases below that age died—a mortality of 26 per cent. Among the 25 patients who survived the operation 4 had suffered from recurrences. Of the remaining 21 cases, 2 had died from other causes, and 19 were alive at date of writing, without having manifested any signs of recurrence, 6 of these having lived for over three years after the operation, 4 over two years, and 9 for periods under two years.—The discussion was continued by Dr. A. Leitch, Dr. T. K. Dalziel, Mr. A. E. Maylard, Mr. R. H. Parry, Dr. J. Crawford Renton, and Dr. J. Grant Andrew.

HUNTERIAN SOCIETY.—A pathological meeting of this society was held on Dec. 6th, Dr. Hingston Fox, the President, being in the chair.—Mr. W. Girling Ball showed the following pathological specimens: 1. Sarcoma of Testicle from a man aged 21, with a history of sudden swelling of that organ three weeks before admission to the hospital. On section, it was found that there was a large hæmorrhage into the centre of the growth accounting for this sudden swelling, which was the first sign of the disease. 2. Hypernephroma of the Kidney, a small encapsuled tumour of the size of a walnut, with hæmorrhage into it. It was situated just underneath the capsule in the renal cortex, and had not invaded the pelvis. It was found quite accidentally in the post-mortem room, not having given rise to any symptoms during life. The patient died at the age of 77, with a fractured base of the skull. There were no other growths found in the body. 3. A small "Traction" Diverticulum of the Œsophagus of the size of a small marble, situated in the anterior wall of the œsophagus, just below the bifurcation of the trachea. It had a distinct neck and was in no way attached to the surrounding tissues. The lymphatic glands in the region were healthy and showed no evidence of old or recent inflammation. 4. A Mediastinal Tumour with a large Secondary Growth in the Kidney. The specimen was shown chiefly to illustrate the extent to which the wall of the heart may be involved without obvious interference with its action. The whole of the anterior wall and the large vessels of the heart were embedded in growth. The posterior wall, however, was free. The growth had been diagnosed as an aneurysm by the radiographer.—Dr. W. H. Kelson showed a series of microscopic slides illustrating the more common affections and pathological conditions found in the throat, nose, and ear, such as polypus, tubercular and malignant disease, syphilis, diphtheria, &c.—Dr. Theodore Thompson showed sections of cords illustrating Subacute Combined Degeneration.—Dr. A. C. Jordan showed skiagrams of chests and lungs illustrating "Peribronchial Phthisis," a condition that will be more fully explained by him in a forthcoming paper.

WIGAN MEDICAL SOCIETY.—A meeting of this society was held on Nov. 30th, Mr. F. L. Angior, the President, being in the chair.—Dr. J. Thomson Shirlaw read a paper on cases of Perforated Duodenal Ulcer in which Mistaken Diagnoses of Lead Poisoning were made. He first read notes of a case occurring in his own practice, a painter who had undoubted symptoms of lead poisoning and who died rather suddenly after a very brief illness, mainly of an abdominal nature, emphasising the fact that on several occasions the colicky pain was relieved by pressure on the abdomen. At a post-mortem examination conducted by himself and Dr. A. Matheson a large posterior duodenal ulcer was found which had perforated into the lesser peritoneal cavity. There were also marked changes in the kidneys, one of which was enlarged and the other contracted. He subsequently read notes of seven or eight other cases where from the symptoms present, the occupation, &c., a diagnosis of plumbism had been made, in all of which were found post mortem one or more perforated ulcers in the duodenum. Next Dr. Shirlaw recalled the classic symptoms of perforated ulcer of the duodenum, compared these with the symptoms in his own case and the others mentioned, and drew attention to the great difficulty of arriving at a correct diagnosis, not only as between duodenal ulcer and lead poisoning, but of duodenal ulcer itself. He then described the post-mortem appearance of the alimentary tract in chronic lead poisoning and in lead poisoning experimentally produced in rabbits, and finally propounded the question, "Does lead poisoning predispose to, or cause, duodenal ulcer?"—Ten of the members present took part in the discussion which followed. Of these, Dr. R. Prosser White, certifying factory surgeon for the district, discussed the modern pathology of plumbism, and pointed out that Dr. Shirlaw had broken new ground by suggesting a causal relation between chronic lead poisoning and duodenal ulcer.—Dr. F. E. Wynne, who was present as a guest, gave a short account of an outbreak of lead poisoning at Leigh, and mentioned that in the only case in which a post-mortem examination was made a perforated duodenal ulcer was discovered.—Dr. Shirlaw, in replying, read a number of letters which he had received from medical men of note to whom he had written on the subject, mostly depreciating any idea of a causal relation between the two diseases.—A short paper was afterwards contributed by Dr. R. Buchanan on a Medical Library, and the discussion was adjourned to a future meeting.

MANCHESTER MEDICAL SOCIETY.—A meeting of this society was held on Dec. 6th, Dr. A. Emrys Jones, the President, being in the chair.—Dr. J. B. Burt (Buxton) read a paper on the Nomenclature of the Chronic Arthritic Diseases. The great chronicity of this group of diseases was one of the important causes of the bewildering terminology and classification. By the time the cases came to be examined post mortem secondary changes had occurred; thus diseases with an entirely different beginning might show identical anatomical changes. Those secondary changes chiefly responsible for obscuring the clinical and pathological picture were due to wear and tear. Mr. Lane had already proved that the excessive use of a healthy joint led to the formation of osteophytes, bony outgrowths, and destruction of cartilage. Slides were shown illustrating these formations in the cobbler's thumb, the miner's right hip, and

[1] Brit. Med. Jour., Oct. 1st, 1910.

in the left knee of a man with a right hemiplegia. There was also a demonstration of the bones of horses suffering from bony spavin, ring bone and side bone to prove that bony formations might be produced by concussion alone. It was suggested that similar changes in diseased joints were due to wear and tear. Various facts proving this were quoted, and it was shown that the chronic diseases where movements were encouraged, such as chronic gout and senile arthritis, were the diseases in which bone formations were most often found, whereas those diseases where there was great infiltration of the ligaments, severe destruction of bone, or great pain on movement, very rarely showed osteophytes. But if this latter group improved sufficiently for the joints to be moved and thus exposed to wear and tear, then, and then only, did they find osteophytes and bony additions. The clinical and X ray features of the named types of arthritis were compared and it was shown that absence of bony change, atrophied and hypertrophic bony changes might occur as a different phase of the same disease. Hence a nomenclature based on X ray findings was valueless. Up to the present time the terminology had depended on the clinical and pathological findings. The present confusion proved it a failure. This reduced them to a classification founded on etiology. Infective, neuropathic, degenerative, and metabolic were suggested as the four main group names in the classification of chronic arthritic diseases.

Reviews and Notices of Books.

The Disorders of Post-Natal Growth and Development. By HASTINGS GILFORD, F.R.C.S. Eng. With 65 illustrations. London: Adlard and Son. 1911. Pp. 727. Price 15*s.* net.

THE author begins by introducing us to Sir Jonathan Hutchinson and "his marvellous clinical insight" in connexion with a case of premature old age engrafted upon or running side by side with a condition of immaturity or infantilism. The study of this case led Mr. Gilford to the discovery of another form of infantilism—obviously not common infantilism—distinguished by delay of development. These two morbid conditions, spontaneous and premature senile decay, or "progeria," and spontaneous persistent immaturity, or "ateleiosis," furnished him with matter for cogitation and led to a consideration of the larger question of differences between growth and development and between the growth and development which go on in the whole man, in his individual organs and in his individual cells. After dwelling on the marked artificiality in the classification of disease the author proceeds to define his subject. Human development does not end at birth; indeed, it may be said only to begin at that epoch, so that the prenatal period is no more than a genealogical introduction to the forthcoming chapters of development. The author's contention is that most of the diseases to which we are subject are diseases of growth or of development, and that by far the larger number of these do not begin until after birth. Parts of this work have appeared in various journals, and the first skeleton of the subject appeared in THE LANCET in 1900. Though the original articles have been much modified they may be said to constitute the framework of this book.

Part I., extending to about 130 pages, deals with "general considerations." That the author's outlook is both wide and philosophical we may gather from the fact that he claims that we must look upon not only the clinicians and the laboratory pathologists as our leaders but also on such men as Darwin, Galton, Mendel, and Bateson, and must regard them as being as truly pioneers of medical science as Sydenham, Trousseau, or Laennec. He incidentally remarks that one of the most neglected departments of medicine is historical medicine, and that biology must be our guide as we thread our way through the intricacies of the diseases with which he deals. The first part is divided into 11 sections, and is devoted to an explanation of the terms "growth" and "development," and to a definition of those diseases or disorders which are essentially natural processes, dislocated from their proper setting, and either falling short of their proper degree or carried to an unhealthy excess. The facts are marshalled in orderly sequence. Growth and nutrition, though intimately related, are distinct processes, and they, with development, constitute a trinity which the author likens to the three primary colours of the spectrum. Each has an individual existence, but under natural circumstances is so blended with the other two as to lose its identity. The author then proceeds to discuss the relations of normal development to: (1) the cell; (2) the organs; and (3) the complex animal.

Development, according to the author, is a qualitative process of two kinds, ontogenetic and phylogenetic, while growth is a quantitative process. Moreover, development is coterminous with life, and is either progressive or retrogressive. Development and degeneration are often spoken of as if they were two distinct processes, whereas they are merely different phases of the same process. This leads to an interesting study of the structural changes in senile decay, whence it appears that the tissue changes of old age are to be known quite as much by the re-appearance of embryonic characters as by actual decay; while senile degeneration and retrogressive development are identical. These two propositions furnish the keystone to the whole subject of perversions of development. Defective control is the main distinguishing feature of the tissue changes alike in second childhood and in first childhood.

Development itself is the outcome of two opposing tendencies—one, heredity, conservative in nature; the other, variation, which is changeable. It is either reactionary or progressive. The author is careful to define and illustrate the separation of the disorders of growth and of development from other diseases, such as those of extrinsic origin due to external agents, the most important of which are the toxins.

Amongst the diseases of intrinsic origin, the most important are pre-natal malformations and tumours. An elaborate account is given of the causes of tumour growth, amongst the chief causes discussed being lead, alcohol, and the toxins of tubercle and syphilis. The innocent tumours are cryptogenous, sporadic, sometimes hereditary, progressive, and incurable by drugs, while cancers—the term is used in a wide sense to include sarcomata and is taken as synonymous with "malignant disease"—in addition are rhythmic or intermittent in their course, and malignant or lethal. The innocent tumours are growths, the malignant degenerations. There are also diseases of mixed intrinsic and extrinsic origin, such as chronic Bright's disease, cirrhosis of the liver, goitre, leukæmia, &c. Degeneration, infantilism, and senilism are then defined and illustrated.

Part II. (pp. 141–211) deals with post-natal growth and development of *cells*, including innocent tumours, defective development or infantilism of cells, premature degeneration or senilism of cells—e.g., cancers, including their clinical characters, the relation of the cancer process to allied conditions, the structure and pathology of cancer, multiple cancers, and the relation of cancer to old age. One point may be noted, that 80 per cent. of all cancers in males are of the alimentary tract, whereas in 80 per cent. of all females they affect the organs of generation and lactation. Before the age of 35 cancer is more common in women than in men. As to the use of arsenic in this disease, the author states that "one can only say that there is apparently more evidence in its favour than there is for any other drug, and that it ought to be given in every case of cancer, whether operated

on or not" (p. 179). Cancers are not due to a generalised infection; they are local disturbances.

Part III. (pp. 215–466) relates to *organs*, and is particularly interesting. It is divided so as to deal with (1) external organs in the following order: the extremities, the cavity of the nose, muscle, and the breast; (2) the fibrous or parenchymatous group, including the liver and its cirrhoses, the kidney and primary Bright's disease, the nervous system, the gastrc-intestinal tract, the arterial system, and the uterus; (3) the cellular or parenchymatous group—e.g., blood, which is considered as a true tissue, thymus, spleen, and lymph glands; and (4) the skeletal group, such as overgrowth of the skeleton, including rickets as a minor variation, defective development or infantilism, osteomalacia, osteitis deformans, and arthritis deformans.

Part IV. (pp. 471–686) treats of the disorders of general growth and development as they affect that combination of cells and organs which constitutes the *man*. First, the abnormal defect of growth known as dwarfism is considered, including phylogenetic or racial dwarfs, and ontogenetic or individual dwarfs. Then gigantism, or excess of growth, abnormal immaturity or infantilism, and premature senility, senilism, precocity, centenarianism, and such general disorders or anomalies of sex as under-development or over-development characterised as feminism and masculinism. There are interesting chapters on obesity, myxœdema, acromegaly, idiocy, and cretinism, while a particularly full account is given of the rare diseases known as ateleiosis and progeria, both of which subjects are illustrated by several striking portraits. Most of the illustrations have reference to Part IV. In regard to the subject of gigantism we would ask the author to glance at the work of Launois and P. Roy, "Études Biologiques sur les Giants." In Part V. the author gives a general summary, and states his conclusions with becoming modesty.

This is, indeed, a most thoughtful and valuable volume, full of interesting details and suggestive analogies, obviously the outcome of much critical examination and study of disease in some of its less-known aspects. We have given throughout this notice the author's views, largely without comment. He remarks that his book is still far from complete, and that some day he may deal with what has been omitted. He seeks to establish his conceptions on a biological basis and to show that a common principle runs through the manifestations alike of the phenomena which constitute health and of those that are grouped as disease. We think that the physician, the pathologist, and the biologist will agree with the author that he has succeeded "in showing that that which constitutes disease at one time or from one aspect is normal at another time or from another aspect—that the same process may be either biological or pathological, according to the view from which we regard it."

Clinical Surgery. (Oxford Medical Publications.) By C. B. LOCKWOOD, Surgeon to St. Bartholomew's Hospital. Second edition. London: Henry Frowde, and Hodder and Stoughton. Pp. 389. Price 5*s.* net.

THE value of clinical lectures depends chiefly on the fact that in them the student obtains a view of the subject from a different point of view than that afforded him in lectures on principles or in systematic text-books. The true clinical lecture deals mainly with the clinical aspect of the cases, and it should be illustrated by the relation of cases to enforce the main points. Mr. Lockwood has done well to reprint these lectures, and we are glad to see that they have attained to a second edition. They are written as they were spoken, and though when read they cannot have all the force of spoken words, yet they are wonderfully alive, and rivet the attention by their earnestness and by the recognition that they are based on a thorough knowledge of the subject with which the author is dealing.

Let the reader open the book where he may, he will find something to interest him, some point of importance to which his attention is directed. In this edition there has been added a lecture on fracture of the patella and one on the amputations at the hip and shoulder.

Immune Sera: a Concise Exposition of the Main Facts and Theories of Infection and Immunity. By Dr. CHARLES FREDERICK BOLDUAN, Bacteriologist, Research Laboratory, Department of Health, City of New York. Fourth edition. London: Chapman and Hall. New York: John Wiley and Sons. 1911. Pp. xi. and 226. Price $1.50.

THE fourth edition of Dr. Bolduan's book has undergone extensive revision and enlargement, and now constitutes a very complete and readable summary of the main facts and theories in the field of immunity. Starting with an account of antitoxins, including the nature of toxins and the allied substances known as toxons and toxoids, the author deals consecutively with agglutinins, bacteriolysins and hæmolysins, precipitins, cytotoxins, and opsonins. A section is next devoted to snake venoms and their antiserums. A brief account of the phenomena of anaphylaxis is followed by a section on infection and immunity, considered in the light of the preceding sections and of other recent researches. A few pages are devoted to the subject of bacterial vaccines, and the last chapter deals with the principles underlying the treatment of syphilis with salvarsan. In a series of appendices a brief account is given of the Wassermann test for syphilis and of Noguchi's modification of this, of the method recommended for examination of the blood preparatory to transfusion, and of various less-known tests, such as the meiostagmin reaction, the cobra-venom test, and so forth. In each section the matter is first dealt with historically—a method which cannot be too highly recommended. The accounts given of modern research are clear and impartial, the author not hesitating to point out difficulties in such matters as Ehrlich's side-chain theory, and criticising some practical methods, such as Wright's control of vaccine injections by estimation of the opsonic index. We should have been glad if he had carried this procedure somewhat further and set out a little more definitely the conclusions he has himself arrived at in questions in which there is conflict of opinion. But we realise that in the obscure field of immunity no approach to certainty has yet been reached, and that consequently dogmatism is unjustifiable. The book has been much improved since its first appearance, and we cordially commend it in its present form.

Du Rôle de la Cholésterine dans le Développement de l'Artério-sclérose et de l'Athéroma, Étude Clinique et Thérapeutique. Par M. le Dr. G. LEMOINE, Professeur de Clinique Médicale à la Faculté de Médecine de Lille. Paris: Vigot Frères. 1911. Pp. 62. Price 1.50 francs.

IN this small book Professor Lemoine records some ingenious speculations as to the part played by cholesterin in the animal economy. He affirms that this substance is by no means excrementitious in nature, but that it and its compounds in the body act as antitoxins, enabling the organism to fight against infections and toxins, more especially against tuberculosis. He finds that there is a deficiency of these substances in the tissues of patients suffering from tuberculosis, and he treats them by means of cholesterin and of lipoids extracted from the liver. On the other hand, he believes that in other individuals of gouty

or arthritic habit the antitoxic function of the liver is developed in excess and leads to an excessive formation of cholesterin bodies, constituting a condition of cholesterinæmia. He has found experimentally that cholesterin is capable of raising blood pressure, and he believes that the excess of this substance in the blood is the cause of hypertension and leads further to the deposit of cholesterin in the walls of the vessels, constituting the essential lesion in arterio-sclerosis and atheroma, the calcareous and other changes being regarded as secondary. He maintains that stout people, even of gouty type, usually escape high tension and arterial changes, which he explains by supposing that their superabundance of fats serves to dissolve any excess of cholesterin which they may form. On these suppositions he has evolved a treatment for arterio-sclerosis which consists in the administration of a "sclerolytic" solution prepared from ethereal extracts of liver from which the cholesterin bodies have been removed and to which certain salts, such as sodium phosphate and sodium glycerophosphate, have been added. Although some experimental and clinical evidence is adduced to support these views, Professor Lemoine's contentions appear to us highly speculative.

Scientific Memoirs by Officers of the Medical and Sanitary Departments of the Government of India. New Series, No. 46. *Malaria in the Punjab.* By Major S. R. CHRISTOPHERS, M.B. Vict., I.M.S., Assistant to the Director, Central Research Institute, Kasauli. Calcutta: Superintendent of Government Printing, India. 1911. Pp. 135. Price 2 rupees, or 3*s.*

THIS volume of the Scientific Memoirs constitutes a very complete exposition of its subject. In the introduction the author gives an account of the physical features, the population, and the rainfall of the province of which it treats. This is followed by a chapter on the autumnal epidemic malaria of the Punjab; although the latter has so dry a soil, yet the recorded death-rate from fevers is higher than that for most parts of India, whilst a very marked feature of the disease is its seasonal character.

In Part II. the autumnal epidemic fulminant malaria is considered, and the epidemic of 1908 and its distribution are described; it affected to greater or less extent almost the whole of the Central and Eastern Punjab. Notice is taken of the previous epidemics in the Punjab. The conditions at Amritsar and other towns are described, as also those in rural areas. Other points noted in this section are the conditions in non-epidemic areas and in epidemic areas in non-epidemic times. The part concludes with some observations concerning epidemic and endemic malaria. In Part III. are considered the determining causes of fulminant malaria with respect to the anopheles in the Punjab, the rainfall and temperature, the physical features of the country, and the human factor. There seems very little doubt that the two factors, rainfall and scarcity, are the determining causes of the epidemic malaria of the province. Part IV. contains a most interesting account of the experimental work performed concerning the mechanism of fulminant malaria, the nature of intense malaria, and the spleen-rate and parasite-rate, and the relations of these two rates to epidemic conditions are fully set forth. Finally, this section concludes with the account of experiments upon the quantitative factor in the transmission of proteosoma to sparrows by the bites of culex.

Major Christophers, as the result of the foregoing research, comes, amongst other matters, to the following conclusions: That in the Punjab malaria is manifested in two ways—viz., as "endemic malaria" and as "autumnal epidemic" or "fulminant malaria," of which the latter is by far the most important considered in an economical sense; that past epidemics have affected all parts of the submontane tracts, but have shown a special frequency over certain areas; that epidemic malaria attacks most severely those communities already showing a high degree of endemic malaria; that excessive mortality and its conspicuously infantile character especially characterise the epidemic conditions; and that the determining causes of epidemics are excessive rainfall and scarcity. The Memoir concludes with the subject of the prophylaxis of malaria in the Punjab, the first step of which must be the removal or prevention of flood water, and until drainage can be instituted satisfactorily the use of quinine must be pushed to the utmost.

Rose and Carless's Manual of Surgery for Students and Practitioners. Eighth edition, revised by ALBERT CARLESS, M.B., M.S. Lond., F.R.C.S. Eng., Professor of Surgery in, and Surgeon to, King's College Hospital. London: Baillière, Tindall, and Cox. 1911. Pp. 1406. Price 21*s.* net.

THIS is the first appearance of this work since the death of Mr. Rose, and though it retains, and for many years will retain, its old title, it represents the views of its editor, Mr. Carless. Almost from the moment of its first issue it took the place of the most widely read work on surgery in this country, and this position it has held ever since. As time passes it has grown in bulk, until now it can hardly be looked upon as one of the smaller manuals on the subject, for the volume contains more than 1400 pages of by no means large print. This increase in size has been mainly due to the ever-extending bounds of surgery; and we can hardly wish that the work were any smaller than it is, for it is all so well written, so clear, and so well fitted for the mind of the student. It is surely needless to say more than that it has been brought by its editor thoroughly up to date, that it contains all that the student will be required to know at his examinations, and that anyone, be he student or in practice, will be able to find here a full description of any surgical disease or operation about which he may wish to obtain information. The book is wonderfully free from errors, but we would point out that on p. 333, in the description of Fig. 106, a certain structure is spoken of as the "internal jugular artery."

La Poliomyélite Epidémique (Maladie de Heine-Medin): Étude d'Ensemble Suivie d'une Contribution à l'Étude des Méningomyélites et des Méningites à Médullo-virus de Landsteiner et Popper. Par le Docteur GEORGES SCHREIBER. Paris: J. Steinheil. 1911. Pp. 365. Price 10 francs.

RECENT researches, both epidemiological and pathological, have considerably increased our knowledge of the disease variously known as poliomyelitis, infantile paralysis, and Heine-Medin's disease, while the occurrence of epidemics in several countries has brought it into prominent notice. The researches upon the causal agent by Landsteiner and Popper, Flexner and Lewis, and Levaditi have demonstrated that this is an ultra-microscopic agent, which is capable of conveying the infection to chimpanzees and monkeys. In this book Dr. Schreiber presents an interesting and full account of this disease from the clinical, pathological, and epidemiological points of view. The bibliography at the end of the book extends to 38 pages and is well arranged. The subject matter is exhaustive and is illustrated by figures, tables, and brief records of cases selected from some of the original papers, so that it forms a most convenient and valuable addition to the literature of the subject, and it appears at an opportune time. Dr. Schreiber recognises the following clinical varieties of the disease: spinal, bulbar, cerebral, meningeal, ascending, descending, ataxic, painful, and abortive types. He describes the various experiments that have been carried out with the supposed causal agent, which he refers to as the medullo-virus of Landsteiner and Popper, and gives in detail the pathological appearances found in fatal

cases of the disease in the human subject, as well as in the experimental disease in the monkey. He describes the clinical features of the different forms and discusses their diagnosis. He brings forward reasons for supposing that some cases of Landry's paralysis are due to the medullo-virus, constituting the ascending form of poliomyelitis, to which he draws attention.

The second part of Dr. Schreiber's book is devoted to a consideration of the meningeal symptoms that may accompany the disease. These may precede the paralytic stage, in which case he describes the condition as a meningo-myelitis; or they may be the only symptoms, in which event he classes the cases as meningitis due to the medullo-virus. The latter condition constitutes one of the abortive forms of the disease. Instances of both these varieties are described as occurring in the epidemics in various countries. A number of illustrative cases are briefly described.

LIBRARY TABLE.

Transactions of the Glasgow Obstetrical and Gynæcological Society. Vol. VII. Sessions 1908-1909, 1909-1910. Glasgow: Alexander Macdougall. 1911. Pp. 20 and 207.—As these Transactions are records of the papers and specimens shown before the society for the sessions 1908-1909 and 1909-1910, a good deal of the information contained in them is already ancient history when the volume is published in 1911. For example, the first paper relates to a lantern and microscopic demonstration of an early human ovum (the Teacher-Bryce ovum) about which a book has already been published and noticed in THE LANCET of Oct. 3rd, 1908; while another important communication to the society—namely, a paper by Professor Schauta on the Treatment of Labour in Contracted Pelves, was also noticed in THE LANCET of Dec. 25th, 1909, in the Annus Medicus. Some of the more important papers contained in the Transactions are those on Pyelitis Complicating Pregnancy and the Puerperium, by Dr. W. D. Macfarlane, Jun.; Ovarian Tumour Complicating Pregnancy, Labour, and the Puerperium, by Dr. G. Balfour Marshall; an interesting address by Dr. J. Munro Kerr on Advances in Gynæcology in Recent Years; the Management of the Ureters in Abdominal Pelvic Operations, by Dr. R. Cochrane Buist; the Ureter in Cancer of the Cervix Uteri, by Dr. Archibald Leitch; and Modern Views of the Treatment of Fibroids of the Uterus from their Pathological and Clinical Standpoints, by Dr. J. Nigel Stark. The volume also contains very interesting reports on the work of the Glasgow Maternity and Women's Hospital for 1909, by Dr. David Shannon, as well as a report on 156 consecutive laparotomies performed in the gynæcological clinic of the Glasgow Royal Infirmary during the year 1909, with notes on the technique adopted, by Dr. G. Balfour Marshall.

Pharmaceutical Formulas; being the "Chemist and Druggist's" Book of Useful Remedies for the Drug Trade, Collated Chiefly from the "Chemist and Druggist" and the "Chemists' and Druggists' Diaries." By PETER MACEWAN, Phar. Chem., F.C.S., Editor of the *Chemist and Druggist*. Eighth edition, with a Supplementary Chapter containing the more Recent Formulas and Appendices comprising Matters relating to the Compounding and Sale of Pharmaceutical Products. London: *The Chemist and Druggist*. 1911. Pp. 1040. Price 10*s.* net; by post 10*s.* 6*d.*—The eighth edition of this useful work, of which the first edition was published in 1898, has undergone a thorough revision, with the result that there are 450 alterations and annotations in the text, while the new formulas number more than 400. Some idea of the wide scope of the book may be gained from the chapter headings: Toilet Preparations and Specialities; Preparations for the Hair; Dental Preparations; Perfumes; Beverages; Culinary and Household Requisites; Horticultural and Agricultural Preparations; Writing Materials; Varnishes, Polishes, and Stains; Lozenges; Miscellaneous Preparations; Photographic Chemicals and Preparations; Galenical and Medicinal Preparations; Bacteriological and Microscopic Work Preparations; a supplementary chapter on "Skin Creams"; and an Appendix of Weights and Measures, Medicine Stamp Duties, Use of Methylated Spirit, the Rideal-Walker Test for Disinfectants, Food and Drug Standards of Australia and the United States, Proprietary Medicines in Canada, Garden Pests, and Board of Agriculture Leaflets. There is a very full index. Many of the subjects are introduced by a brief descriptive essay. The synoptical reference list, prepared for the seventh edition, now having lost its interest and utility, has been omitted so as to make room for the hundred or more pages of new formulas that have been added. It will be seen that the book embraces a wide range of information that will be found useful, not only to druggists, but to medical men, dentists, physiologists, photographers, veterinary surgeons, farmers, gardeners, housewives, and, in fact, to almost everyone.

Zoo Folk Interviewed. By W. J. ROBERTS, F.Z.S. London: T. Werner Laurie. 1911. Pp. 215. Price 3*s.* 6*d.* net.—This book is a charming description of the dwellers in the grounds of the Zoological Society in Regent's Park. Mr. Roberts has a keen sense of the humorous side of animal life as well as an intimate knowledge of the habits of the creatures he describes, and he has anecdotes to tell and interesting information to impart which will be appreciated by everyone. Lions, tigers, elephants, bears, camels, giraffes—all the obvious animals—are described in a manner at once interesting and instructive; while the chief points of the animals whose appearance does not immediately attract the attention of the visitor are detailed in a way that will stimulate the desire for a better acquaintance with them. Incidentally the curious will learn also how it is that the squirrel has made the trees of Regent's Park its home, and will be enlightened as to the relation between the camel-hair brush and the animal whose name it apparently bears. The author has stories to tell, new and old. The story of the observer who, wishing to see whether the chameleon could change to two or three colours at the same time, placed the poor creature on a piece of tartan, with the result that it "bust 'is little self" in the attempt is old; but the story of the servant who, when asked by her mistress to bring the tortoise out of the coal-cellar, where it had been placed for protection during the winter, exclaimed, "What, that bit of stone alive? Why, that's what I've been breaking the coal with!"—is new to us. Another side of the author's treatment of his subject is indicated by a reference to the Girardinus pœciloides—interesting fish which are reared by the society and dispatched to malaria-infested countries, where they are turned into the rivers. These lively little fish, otherwise known as "millions," have a great fondness for the mosquito larvæ, and it is stated that they are instrumental in keeping the Barbados free from malaria. There are 25 black-and-white illustrations in the book and a coloured frontispiece of George the Mandril, "the fiercest beast in the Zoo," and the author might perhaps have added the ugliest.

Two Hundred Opera Plots. By GLADYS DAVIDSON, author of "Stories from the Operas," "The Old Testament Story," &c. 2 vols. Illustrated. London: T. Werner Laurie. 1911. Pp. 219 and 451. Price 3*s.* 6*d.* net each vol.—All lovers of opera, and many others who merely desire to avoid betraying ignorance, will be glad to have these two volumes, telling in a few plain words the plots of 200 of the best-known operas, from Gluck's *Orpheus and Eurydice*, produced in Vienna in 1762, to Leoncavallo's *Maia*, produced in Berlin last March. The composers represented number 84, and

include, besides all the classical ones, many whose names are but little known to the public at large. Each plot is preceded by a description of its musical character, the names of the composer and of the author of the libretto, the place and date of its first production, and the names of the principal characters. The two volumes contain 15 portraits of composers. There is a table of contents containing the operas under the names of the composers in alphabetical order, and an alphabetical index to the operas themselves. The date when the respective composers lived would have been a useful addition to their names, either in the contents or at the head of the articles, as in Bartlett's "Dictionary of Quotations."

The Physiology of the Human Labyrinth.—The Arris and Gale Lecture, delivered before the Royal College of Surgeons of England on March 18th, 1910, by SYDNEY SCOTT, M.S., M.B. Lond., F.R.C.S. Eng. Cambridge: W. Heffer and Sons, Limited. 1911. Pp. 24. Price 2*s.* net.—This lecture was published in THE LANCET of June 11th, 1910. Those especially interested in the subject will be glad to know that a reprint in stiff covers can now be obtained.

JOURNALS AND MAGAZINES.

Edinburgh Medical Journal.—In a valedictory address to the Edinburgh Obstetrical Society published in the December issue of this journal Dr. F. W. N. Haultain gives some reminiscences of Sir James Y. Simpson's association with that society. Dr. John McGibbon, in the same magazine, discusses repeated Cæsarean section, and records a case in which the operation was thrice performed on the same patient; he believes that there is little or no increase of danger in the second and following operations.

The Dublin Journal of Medical Science.—The need of medical inspection of school children in Ireland is enforced by Dr. O. St. J. Gogarty in a paper published in the December number of this journal. He notes that "every civilised country but our own (Ireland) has its school children medically inspected." Mr. Bertran C. A. Leeper records a fatal case of illness occurring in a woman, aged 20, and resembling Henoch's purpura. No post-mortem examination could be obtained, so that the exact nature of the malady remains obscure. Sir John Moore contributes notes of three interesting clinical cases, one of cirrhosis of the liver and perihepatitis, with jaundice, hæmatemesis, and purpuric symptoms; a second, of pneumonia and empyema, in which recovery followed thoracentesis and injection of antistreptococcal serum; and a third, of mediastinal lymphosarcoma involving the œsophagus, stomach, and liver, and compressing the trachea, loss of voice and extreme dyspnœa being the striking symptoms.

The Medical Chronicle.—The original matter in the November number of this magazine consists of Dr. F. W. Mott's address to the Manchester Medical Society on the subject of "Hereditary Transmission of Disease, especially in Relation to Anticipation." An interesting account is given of the tendency of hereditary diseases to appear at earlier ages in the members of each succeeding generation.

Jahreskurse für Aerztliche Fortbildung. Munich: Lehmann. Price M.16 yearly.—The September number of this Annual Post-Graduate Medical Course deals with affections of the locomotive organs and joints. Professor Lange contributes an article on Chronic Rheumatic Diseases. He divides these into: 1. Mono-arthritis, generally caused by local trauma or strain, with primary affections of cartilage and bony ends. The details of this affection are described in the hip, knee, and foot joints. 2. Chronic Polyarthritis. This is a primary affection of the joint capsule affecting many joints simultaneously, generally those of the fingers and hands. The latter cases are again divided into the afebrile varieties and those accompanied by fever. The tendency in all these synovial affections is to end in ankylosis. In their treatment the use of baths, radium, diet, purgatives, and orthopædic measures is considered. Professor Ludloff writes a most valuable article about the Treatment of Tuberculous Hip-joints. He distinguishes three main types of disease—viz., hydrops, diffuse disease of the synovia, and suppuration. The first variety is very rare. Resection of the joint is to be reserved as a last resource for cases of suppuration or necrosis. The method of extension in the correction of deformities is one which has some danger, but this can generally be avoided by special precautions. The application of a plaster case is regarded by the writer as the method of greatest use. An anæsthetic is administered to abolish muscular spasm, and at the same time any abscess is aspirated. Then the plaster is applied in a position of ease—that is, without any attempt to strain the limb into any special position. Both hip- and knee-joints are enveloped in the plaster, and a walking patten is incorporated in its lower end. It is allowed to remain for as long as possible, certainly for several months at a time. Professor Ludloff speaks from an experience of 1000 cases, and the care with which he describes the details necessary for the treatment makes his article of great value.

The October number deals with infectious diseases. Professor von Pirquet reviews recent work in Measles. The possibility of artificial inoculation has been demonstrated both in the cases of human beings and apes. The remarkable immunity enjoyed by very young infants—i.e., below six months—is discussed at some length, and the conclusion arrived at that they receive this from the mother's milk, the mother having suffered from the disease herself. The significance of Koplik's spots is referred to. The blood changes consist chiefly in a leucopenia proportional to the gravity of the disease, and usually preceded by transient leucocytosis. Perhaps the most important aspect of measles is the increased liability which its victims show to suffer from subsequent tuberculosis, diphtheria, pemphigus, noma, and pneumonia. The nature and significance of this liability are considered. Professor Nocht writes about Beri-beri. After a careful account of its symptoms and etiology, he discusses the question as to its infectious nature or its dependence on some error of nutrition, and finds it undoubtedly associated with rice-eating. Professor Fraenkel writes on certain aspects of Tuberculosis. He says this disease accounts for more deaths than diphtheria, whooping-cough, measles, scarlet fever, typhoid fever, puerperal fever, diarrhœa, and syphilis together. Every third death between the ages of 16 and 60 is due to tuberculosis. He describes in some detail the advantages of some of the newer methods of detection of the bacillus, laying stress upon the "antiformin" method of segregation. The principal facts relating to the sterilisation of milk and the relationship of human and bovine tuberculosis are shortly discussed. A clear account is given of the various types of tuberculin tests and their control by the opsonic index, and the treatment of the disease with the different forms of tuberculin. The writer takes a very optimistic view of the results of sanatorium treatment, maintaining that in men 55 per cent., and in women 61 per cent., exhibit recovery lasting for three years. Some very interesting figures are given relating to the geographical distribution of the disease and its progress in different countries. In some countries, such as England, Scotland, Wales, and Massachusetts, the disease appears to be steadily decreasing, whereas in others, such as Norway and Japan, it is increasing.

ERRATUM.—In THE LANCET of Dec. 9th we published a review of "Experimentelle Bakteriologie," by Kolle and Hetsch, in which, unfortunately, the price was wrongly stated. The price is not M.30 for each volume but for the complete work.

THE LANCET.

LONDON: SATURDAY, DECEMBER 23, 1911.

The National Insurance Act.

WE publish this week accounts of three important meetings of the medical profession which have been held since the last issue of THE LANCET in Manchester, Birmingham, and London respectively. Our readers were many of them present at one or other meeting, while the lay press has done full justice to them, so that it has not been necessary in our report to set out more than the salient matters; but from these it at once appears that the feeling of the medical profession as a whole is not represented exactly by any of the resolutions which have been passed at the meetings. The resolutions, though similar in character, have not been similar in detail. At the Manchester meeting two resolutions were passed almost unanimously. The first pledged the medical profession to refuse to form a panel under the Act, or to undertake any duties in connexion with it; and by the second a National Medical Union was created to strengthen the hands of the British Medical Association and other societies and committees working in medical interests. At the Birmingham meeting three resolutions were passed, and with some evidence of a diversity of opinion. The first declared that the Act did not satisfy the demands of the medical profession as defined in the "six cardinal points"; the second declared the public interest to be jeopardised equally with the medical; and by the third resolution medical men came into line with the first Manchester resolution, after refusing to accept an amendment designed to allow participation in Local Insurance Committees. In London the first resolution declared that the "six cardinal points" were not guaranteed by the Act, and this was passed almost unanimously. The second resolution differed, however, from the resolution common to Manchester and Birmingham in that it declared, after affirming the fundamental importance of the demands of the medical profession, that medical men should refuse to accept any office for giving medical attendance and treatment under the Act until these demands have been definitely conceded. This was passed with practical unanimity, indeed with the same enthusiasm that marked the reception of the more complete cutting off of future negotiations implied in the Manchester and Birmingham resolution.

It was well known before the meeting in London that some of the supporters of the "six cardinal points" have not been absolutely convinced of the sacrosanct character of these points; that is to say, that a good many medical men have undoubtedly voted in favour of resolutions stating that the "six cardinal points" originally formulated by the British Medical Association are of paramount importance, while meaning that some of these points are of great importance to themselves, and some of them, no doubt, of great importance to other people, especially to the public dependent upon an efficient medical service. At the meeting in London the stand of the profession was transferred to some extent from the "six cardinal points" to a more general demand for just treatment. The meeting clearly elicited the view that the Council of the British Medical Association, however manful its efforts, had not obtained the inclusion in the Act of the "six cardinal points," or of conditions guaranteeing stability to the medical profession. The tone of the speeches was not of a much less intransigent character than those which were made with success in Manchester and Birmingham, and a limited and unwilling hearing was accorded to the supporters of the Council of the British Medical Association. The determination to leave unmentioned as far as possible the matter of the behaviour of the Council in sanctioning Mr. SMITH WHITAKER'S appointment as Deputy Chairman of the Commissioners broke down on several occasions. These personal matters, which are of the first importance to the British Medical Association but not of similar significance to the medical profession or the public, have somewhat overshadowed the constructive resistance that should be properly offered to the Act. The "six cardinal points," which the Council of the British Medical Association consider to be substantially secured by provisions in the Act, and which others cannot find therein with the same ease and clearness, are no longer the only basis of medical opposition to the Act. It is generally felt that by the Act it is proposed to buy the profession of medicine outright and at the lowest possible price.

The importance of the London meeting has been that by it there has been formed a continuous line of policy for the great English centres. Sir W. WATSON CHEYNE, in the quiet weighty words with which he opened the proceedings, sufficiently showed that the leaders of the profession are as alive to the possible evils underlying the Act as the general practitioner whose services it is proposed to commandeer upon vague and unsatisfactory terms. Sir ALFRED PEARCE GOULD criticised the Act upon broader lines than is signified by adherence only to the "six cardinal points," and proved that effective common action can ofttime be taken by those who do not see eye to eye with each other in details. We regret that a patient hearing was not given to Sir VICTOR HORSLEY and Dr. J. H. KEAY, for those who feel deeply that the Council of the British Medical Association is placed in a position that requires explanation ought, we think, to be willing to hear that explanation. There is force in the view that the Council owes such explanation rather to the members of its constituency than to a general meeting of medical men, but in the course of the speeches at the meeting the conduct of the Council was impugned, and the defence offered should have been heard.

Housing in Rural Districts.

IT is very generally admitted that a vast amount of the unwholesome and insanitary conditions existing in various parts of the country is capable of being remedied through the provisions of the various Public Health Acts which have been passed by the Legislature during the past 40 years. If those Acts were adequately enforced an immense improvement would be effected in the surroundings of a large number of people, particularly in the small towns and rural districts. The machinery for carrying out that improvement already exists, but unless it is put in motion it might as well be non-existent. As regards the housing of the working classes it is notorious that sanitary authorities have been particularly inactive. The Housing of the Working Classes Act, 1890, placed upon local sanitary authorities the obligation of making an inspection of their districts for the purpose of ascertaining the existence of uninhabitable dwellings. but a Committee of the House of Commons reported in 1906 that in rural districts especially the authorities had deplorably failed to fulfil their obligations in this respect. The Local Government Board has endeavoured through its medical inspectors, by persuasive communications and in other ways, to bring about improved conditions, but with only very partial success.

However, indications at last show that the authorities are awakening to a sense of their responsibilities. Hitherto the principal channel of communication as to the housing conditions of a district open to the Local Government Board has been the annual report of the medical officer of health. That official was directed to give in his report an account as to the adequacy and fitness for habitation of the house accommodation of the working classes residing in his district, as to the sufficiency of open-air space about houses and the cleanliness of their surroundings, and as to the supervision over the erection of new houses. Obviously his observations might be, and as a rule were, of a very vague and general character. With the coming into force of the Housing, Town Planning, &c., Act, 1909, and the Regulations of the Local Government Board as to the inspection of houses which have been made under the provisions of that Act, the Board will now be able to ascertain much more accurately and particularly which authorities are neglecting their duties and which are actively carrying them out. But under the Housing (Inspection of District) Regulations, 1910, a medical officer of health is required to state in his annual report the number of dwelling houses found on inspection to be unfit for human habitation, the number of representations he has made with a view to the making of closing orders, the number of closing orders that have been made, the number of houses made habitable both before and after closing orders have been made, and the general character of the defects found to exist. As the regulations have been in force for a complete year the reports of medical officers of health which will be issued during the next few months should show to what extent the latest Housing Act has proved successful in improving the dwellings of the working classes. If, as is almost certain, in some districts it is found that the authorities have continued their policy of inaction and have failed to exercise their powers there should be no hesitancy on the part of the Local Government Board in putting into force the compulsory powers contained in the Housing Act of 1909.

Annotations.

"Ne quid nimis."

ACUTE POLIOMYELITIS AND CEREBRO-SPINAL FEVER.

IN an annotation published in last week's issue of THE LANCET under the above heading we referred to a memorandum issued by the Permanent Secretary of the Local Government Board urging the desirability of making both these diseases notifiable. In this memorandum it was pointed out that at the commencement of some of the outbreaks of acute poliomyelitis some difficulty was experienced in diagnosis, owing to the similarity of the symptoms to those of cerebro-spinal fever. We have received a copy of a note by Dr. J. T. C. Nash, county medical officer of health for Norfolk, dealing with certain aspects of these two diseases, and with the prophylactic measures to be adopted against their spread. He has investigated certain cases of these diseases occurring in his own county. In the first of these he found a child of five years suffering from symptoms of cerebro-spinal fever, a sister having succumbed shortly before from acute poliomyelitis. The cerebro-spinal fluid was investigated by Dr. G. P. C. Claridge, who obtained a Gram-negative coccus indistinguishable from the diplococcus intracellularis meningitidis. It was found that both these children had been visiting a short time before in the neighbourhood of Stowmarket, where an epidemic of poliomyelitis had occurred. The most extensive outbreak in Norfolk of which Dr. Nash has been able to obtain particulars took place in the Downham rural district, following upon an epidemic in an adjoining neighbourhood in the county of the Isle of Ely. The cases in the Downham epidemic were undoubtedly cases of poliomyelitis with distinct paralyses, and some contact or other, direct or indirect, could be traced between several of them. Dr. Nash points out that although among the cases occurring in Norfolk two or three were diagnosed as cerebro-spinal fever, and in one of these, as already mentioned, the meningococcus or diplococcus intracellularis was obtained, it is generally held that poliomyelitis and cerebro-spinal fever are distinct affections caused by different infective agents. At the same time, he sees no inherent difficulty in supposing that the meningococcus may be capable of giving rise to the symptoms of both affections, and remarks that it would be curious if an inflammation of the spinal cord were not sometimes accompanied by symptoms of inflammation of the membranes and *vice-versa*. In this connexion it may be of interest to refer to a review published on p. 1778 of this week's issue of THE LANCET. Dr. Georges Schreiber, in an interesting monograph upon Epidemic Poliomyelitis, discusses in detail the meningeal symptoms occurring in that disease, and suggests that some of the abortive forms present meningeal symptoms only. In the note to which we have referred Dr. Nash insists that contagion in cerebro-spinal fever appears to be effected by means of the mouth and nose of sufferers or of carriers, and states that investigations have shown that in an epidemic of this disease, the percentage of carriers may be as high as 50 per cent. among members of families in which cases have occurred. He believes that a similar condition applies to poliomyelitis, although bacteriological proof is wanting, and he advises the same procedures for contacts of cases of poliomyelitis as are generally recommended for cerebro-spinal

fever. Every person (including the medical practitioner) who comes in contact with a case of either disease should take certain precautions by using antiseptic gargles and by antiseptic spraying or douching of the nose. Pocket handkerchiefs should be boiled, and other measures of disinfection applicable to notifiable infectious diseases carried out. Dr. Nash welcomes the increasing attention now being paid to the human factor in infection—viz., the mucous membranes of sufferers and contacts—and thinks that too much importance may be placed upon so-called disinfection of rooms and articles, which he regards as of secondary value in prophylaxis in comparison with the human factor.

THE WEEK-END IN THE OFFICE.

THE busy arena of commercial life known as "the office" has too often few attractions from the point of view of health. It is very often a badly lit and badly ventilated space, and while in London and old business centres many offices are underground and the personal accommodation is rarely as generous as it might be, in newer centres the provision for the growth of business premises has been unworthy. At the end of the working day some attempt is made to cleanse the office—the duster and broom are brought into requisition. Some dust is removed, some is scattered, and then, as a rule, the office is closed tightly in every direction. There is no pretence to "airing" it, and often enough the shutters are drawn. In the morning there is the same neglect to freshen the air before the day's tasks begin, and the clerk comes back to work in a stale, frowsy air. The condition after a week-end is worse where no pains are taken and no thought given. By carefully shutting all doors and windows, and excluding the light by pulling down the blinds or shutters, the air is allowed to stagnate over Saturday night, Sunday, and Sunday night, and the purifying influences of sunlight and fresh air are refused. It follows that any infective materials are left infective, and the dose must accumulate day by day, week by week. Under the conditions described, in fact, the office may become a breeding ground of disease—there are no light and air admitted to destroy the vitality of disease organisms. We are certain that an immense advantage to the health of those occupied in offices would accrue if steps were taken over the week-end to "air" and freshen the offices in our great cities, and to admit the light freely during the weekly vacation. That it is not done now may be witnessed by anybody walking through the streets of the City of London, or through the commercial parts of any great centre, on a Sunday. In the majority of cases the banks, insurance offices, and warehouses are locked up tight, door and window. The hygienic condition of these places would be vastly improved if the opportunity were taken of admitting air and light freely through them during the time the workers are taking their rest and recuperating.

THE EXPECTATION OF LIFE IN CONSUMPTION.

IN his annual report for 1910 Professor Saugman, of Vejlefjord Sanatorium, deals, among other matters, with the fate of the 1359 patients who were treated at the sanatorium in the period 1900 to 1908. He succeeded in tracing all but 28; but the task of writing to former patients for particulars, involving in some cases the despatch of three letters to each patient before an answer was obtained, has cost so much time and money that he proposes following for the future only the fate of patients in the two earliest and the two latest years of treatment. 51 per cent. of all the patients were fit for work at the end of 1910, while only 3·5 per cent. were still invalided by consumption, 40·5 per cent. had died from this disease, and 2 per cent. had died from other diseases. As 63 per cent. of the patients were in the third stage of the disease at the commencement of treatment, the above results are unusually good. With regard to capacity for work, 89·1 per cent. of patients treated in the first stage of the disease fulfilled this condition, while only 3·2 per cent. had died from tuberculosis; 2·6 per cent. had died from other diseases, and 3·7 per cent. were not traced. Of the patients treated in the second stage of the disease, 75·2 per cent. were still fit for work, and 16·3 per cent. had died from tuberculosis. Of the patients treated in the third stage of the disease, 32·6 per cent. were still fit for work, while 53·8 per cent. had died from tuberculosis. Professor Saugman concludes that with suitable sanatorium treatment 90, 60, and 22 per cent. of consumptives in the three stages of the disease respectively may expect to be fit for work eight to ten years after treatment. Attention is drawn to the improvement in the sanatorium results during the latter years, especially with regard to patients in the third stage of the disease. This is accounted for by the increasing number of patients in this stage who have been treated by the induction of an artificial pneumothorax, as many as 22 being thus treated in one year. This treatment has now been adopted for several years at Vejlefjord.

DAMAGED TOMATOES AND TOMATO SAUCE.

Mr. B. J. Howard[1] has spent much time in the field and factory studying the moulds and bacterial contents of tomatoes and tomato pulp as it goes through the process of manufacturing sauce or ketchup. From his records it appears that in the United States home-made sauce is practically free from moulds, while that made in factories is frequently contaminated with moulds. Low-grade sauces are frequently made from refuse and rejected tomatoes. One cubic centimetre of the resulting sauce may contain as high as 300,000,000 organisms, with a minimum of 10,000,000. Considerable light has recently been thrown on the changes that take place during the spoiling of tomatoes by Mr. Raymond F. Bacon and Mr. P. B. Danbar.[2] Tomatoes contain on the average about 6·4 per cent. total solids, of which 3·5 per cent. is invert sugar, 0·5 per cent. citric acid, 0·6 per cent. ash, 0·9 per cent. protein, 0·85 per cent. crude fibre, and about 0·05 per cent. fat. When tomatoes spoil as a result of the life-processes of bacteria, yeasts, and moulds the sugars are rapidly used up, being changed principally into acetic and lactic acids, alcohol, and carbon dioxide. In most cases the citric acid also is rapidly decomposed, so that the amount present serves as a valuable indication of the extent of decomposition. It is very easy to detect spoilage in tomato pulp or canned tomatoes, as such products, when perfectly sound, contain no volatile acids and a considerable percentage of citric acid and invert sugar, whereas, when spoiled, quite large amounts of volatile acids are present with little or no invert sugar or citric acid. But in sauces and other manufactured products of the tomato the legitimate addition of sugar and acetic acid in varying proportions renders ordinary analytical data of less value in deciding as to the soundness of the tomatoes from which these products were made. It has been found, however, that the nature and quantity of the acids present and certain analytical ratios seem to give some information on this point. A good tomato sauce is characterised by a high citric acid content and very little lactic acid, whereas spoiled tomatoes will have a low citric acid content and a high content of lactic acid. It appears that in tomato canneries it is customary to set aside the small and defective fruit, together with the skins, cores, and pieces of tomatoes that have been canned and

[1] Bureau of Chemistry, United States Department of Agriculture, Circular No. 58.
[2] Bureau of Chemistry, United States Department of Agriculture, Circular No. 78.

cook these to prepare a tomato pulp for the subsequent manufacture of sauce or ketchup during the dull season that follows the busy canning period. This pulp is thus stored for a considerable time in barrels which are not tight enough to prevent contamination with organisms and consequent fermentation during storage. The decomposition might be avoided by rejecting decayed tomatoes, sterilising the material, and storing it in lacquered tin cans. Manufacturers make use of two other processes. In one, the gravity process, the pulped tomatoes stand until the tomatoes rise as a result of fermentation; the clear liquid is then run off. In the other process, the tomatoes are mixed with a large amount of salt and allowed to ferment until the sugars, citric acid, and other changeable substances have disappeared; the product is then filled into cans without any sterilisation. The original papers, to which reference has been made, contain much experimental data, which will doubtless lead to the adoption of more careful methods of manufacture in the future. It would seem to be desirable to avoid all unnecessary decomposition, preserving the acids and sugars in the same condition in which they are present in fresh and ripe tomatoes. This fruit is so abundant, appetising, and wholesome that a plentiful supply, in the canned form, is of great value as a food in the winter months. The substitution of a decayed and fermented mush for the sound fruit is a crime against the public health, whether caused by cupidity, neglect, or ignorance.

THE TREATMENT OF AMŒBIC DYSENTERY WITH HEROIC DOSES OF BISMUTH SUBNITRATE.

IN India amœbic dysentery has been very successfully treated and the supervention of hepatic abscess largely prevented by the administration of ipecacuanha, a method of treatment which has recently been urged in emphatic terms, among others, by Major Leonard Rogers, I.M.S., professor of pathology in the Medical College, Calcutta. In the tropical parts of America the use of this drug in cases of amœbic dysentery does not appear to be so greatly appreciated, more reliance being placed upon the employment of bismuth subnitrate. At the eighth annual meeting of the American Society of Tropical Medicine held at New Orleans in May last a paper was read by Dr. W. E. Deeks and Dr. W. F. Shaw, respectively chief of the medical clinic and physician to the Ancon Hospital in the Panama Canal Zone. The authors explain that the treatment of amœbic dysentery (or, as they prefer to call it, amœbic colitis) by ipecacuanha has never appealed to their "physiological common-sense," and for that reason they had never even given it a trial. Moreover, the practice they have for some years followed has proved so satisfactory that they had no reason to resort to any other. Their method comprises complete rest in bed, a generous milk diet, irrigation of the lower bowel by saline or plain water, and the administration of heroic doses of bismuth subnitrate, a heaped-up teaspoonful, equivalent to about 180 grains by weight, being given suspended in almost a tumblerful of plain or effervescent water every three hours, day and night in severe cases, lessening the amount only when improvement is maintained. This treatment is named by the authors the "bismuth-milk-saline method." It has been pointed out that symptoms of poisoning might occur when such large doses of the subnitrate are given, but to this Dr. Deeks and Dr. Shaw reply that they have only met with four such instances among the many cases treated by them in the Ancon Hospital. The chief symptom which caused alarm in the four exceptional instances mentioned was cyanosis, which, however, soon passed off after the administration of magnesium sulphate. This untoward symptom was probably due to the liberation of nitrous oxide or similar gas in the blood through the decomposition of the bismuth salt. It is worthy of note that in all of the above-mentioned cases there existed some serious disease in addition to the dysentery, two of the patients having diffuse nephritis, one cancer, and one pernicious malaria. The medicinal preparations of bismuth are alleged to be "actively antiseptic" and to have a local sedative and astringent action on the mucous membrane of the intestines. The subnitrate does not act upon the specific protozoal organism of the disease, the entamœba histolytica, but upon the associated putrefactive symbiotic bacteria, the presence of which is essential for its growth. During its passage through the large bowel the bismuth subnitrate becomes converted into a sulphide. The nascent sulphur with which it unites is a derivative of the proteids through the action of the putrefactive bacteria; when the latter are destroyed and no further sulphur is liberated the subnitrate passes through the lower bowel white and unchanged. This usually occurs from 10 to 21 days after the commencement of the treatment. The authors contend that the lower bowel can in this way be rendered "antiseptic" as far as putrefactive bacteria are concerned. The convalescence of the patient is shown by the clean tongue, the restored appetite, and the normal temperature, and also by the disappearance of tenderness over the bowel and by the gain in weight. Unfortunately, some persons cannot continue the absolute milk diet which is so essential, but as soon as improvement commences they insist upon returning to solid food, and in many such instances relapses follow. According to Dr. Deeks and Dr. Shaw, the "bismuth-milk-saline method" of treatment of amœbic dysentery gives in almost all cases "a perfect result" if the lines laid down by them are properly followed; they also maintain that it gives "a maximum of cures with a minimum of recurrences and metastatic development, the most frequent of which is liver abscess." They recognise that in some occasional cases surgical interference in the form of cæcostomy may be indicated. From the statistics the authors supply, the method of treatment which they advocate has apparently proved very successful in the Panama Canal Zone.

ACETONE IN INOPERABLE CANCER OF THE UTERUS.

IN the *Maryland Medical Journal* for December Dr. A. Samuels has recommended the application of acetone to check hæmorrhage and lessen discharge and fœtor in inoperable cancer of the uterus. It is easily applied and is harmless, and thus has an advantage over caustics, which are painful and may penetrate so deeply as to injure healthy parts. This treatment was introduced by Dr. G. Gelhorn, of the St. Louis Skin and Cancer Hospital, whose method is as follows. Under anæsthesia the cancerous cavity is thoroughly curetted to remove as much dead tissue as possible. The curetted surface is dried with cotton wool. A Fergusson's speculum is introduced to protect the vagina, the hips are elevated, and through the speculum about half to one ounce of pure acetone is poured into the cavity. The anæsthesia may then be stopped and the patient left in position for from 15 to 30 minutes. The acetone is allowed to run out through the speculum by lowering the table and the cavity is packed with a strip of gauze soaked in acetone. The speculum is removed gradually and the excess of acetone which may have come in contact with the vaginal mucosa is wiped off with wet gauze swabs. The surface is then dried and a cotton tampon is inserted into the vagina to absorb any excess of acetone. The next application of acetone should be made after five or six days. Subsequent applications may be made twice or thrice weekly, according to the symptoms. If the practitioner is without an assistant

the patient may hold the speculum in position. Care must be taken not to allow the acetone to run over the vulva. As a precaution to prevent irritation it is well to coat the vulva and vagina with a layer of petrolatum. After the acetone is allowed to run out the vagina should be swabbed and a large cotton tampon coated with vaseline introduced into the vagina before the speculum is completely withdrawn. The tampon should be removed by the patient in four or five hours. The immediate effect of the application of acetone is a slight oozing, which soon ceases. The surface of the cavity becomes covered with a thin whitish film. A slight discolouration may be seen in some parts. This is due to the action of the acetone upon small bleeding points. The normal vagina is not appreciably irritated. Slight irritation of the skin may result if it has not been previously protected with petrolatum, and an intense burning sensation if the acetone is carelessly allowed to run over the skin, but this soon subsides. The remote result of the application of acetone is marked reduction of the fœtor. The discharge, which at first is profuse and watery, gradually disappears. Hæmorrhage becomes less frequent and less profuse. After three or four weeks the cavity becomes considerably diminished and its walls become smooth and firm. In one case they were so firm that a finger could not remove any friable tissue. With the checking of the hæmorrhages and discharge the general health for a time improves and the pain diminishes. But if the cancer has extended to neighbouring organs the pain may not be relieved, although the discharge and hæmorrhage cease. The use of acetone is contra-indicated when the disease is so advanced that an opening has formed into the rectum, peritoneal cavity, or bladder. Otherwise it may be used without fear, as it is not absorbed.

LEGALISED SUBSTITUTION.

THE art of substitution has reached such a high level nowadays that the necessity for definitions arises. During the last decade high courts, police courts, scientific tribunals, and so forth have had much of their time occupied in considering when it is that certain novel commodities are entitled to a time-honoured name, and so questions like the following have been discussed: What is marmalade? What is beer? What is leather? What is silk? What is champagne, brandy, whisky, port or rum? Many other articles might be mentioned, widely diverse in nature and composition, but having this in common, that they are capable of being handicapped in competition by the introduction of substitutes generally declared to be "just as good." To such interrogatories we may seasonably add, What is plum pudding? The obvious answer would appear to be pudding made in part, at any rate, of plums; yet what is generally called a plum pudding—the Christmas pudding—never contains plums, if we accept the definition of a plum that it is the edible drupaceous fruit of any one of various trees of the genus prunus. As everyone knows, the fruits used in Christmas pudding are generally raisins and currants, both of which are dried grapes. There are several puddings in the cookery books containing raisins which are called by various fancy names, but never "plum pudding"; there is also a pudding (reminiscent of school-days) containing currants, which is called a currant pudding or by offensive terms according to the temper of the speaker. We should not expect these puddings to be called plum puddings, and they never are; but when the currants and raisins appear in the Christmas pudding the product is called a plum pudding. With no logic it is agreed to accept the word plum as applicable to raisins or currants when they happen to be in Christmas pudding. If plum jam were asked for and a grape conserve were wilfully substituted we should expect such a bargain to be regarded as a misdemeanour within the meaning of the Food and Drugs Acts, but whether that should be the case when plum pudding is asked for and a pudding without plums (strictly speaking) is tendered is not so clear. It would no doubt be argued, in case anyone should attempt to interfere with the sale of Christmas puddings, that the customer was supplied with exactly what he expected to get—that is, a plum pudding without any plums.

FATALITIES FOLLOWING THE INTRAVENOUS INJECTION OF SALVARSAN

THE earlier fatalities which followed the use of salvarsan were attributed by Ehrlich to the presence of advanced disease of the nervous or cardio-vascular systems, which he stated were contra-indications to its administration. He claimed that with due care salvarsan was perfectly safe. Unfortunately, several fatalities have been recently recorded, and show that its administration, even in young and robust patients, is by no means devoid of risk. In an annotation [1] we described two American cases in which acute nephritis was produced in young men by an intravenous injection of 0·6 gramme. In one case fatal anuria supervened. The patient at the time of the injection had a characteristic secondary rash, and his urine contained a trace of albumin but no casts. Previously to acquiring syphilis he enjoyed uninterrupted health. In the other case the urine was perfectly normal, but after the injection presented all the signs of acute nephritis. In another annotation [2] we referred to the case of a robust man, aged 35 years, reported to the Académie de Médecine of Paris by M. Hallopeau. For a relapsing palmar and plantar syphilide the patient was given by a practitioner an intravenous injection of 0·3 gramme of salvarsan, which was well borne, and on the sixth day an injection of 0·4 gramme. Congestion of the face, vomiting, and epileptiform convulsions followed, and he died comatose. In the discussion which ensued Professor Gaucher declared that several deaths had followed the use of salvarsan at the Saint-Louis Hospital, and that almost all the patients died in the same manner, with epileptiform convulsions. In the *Medical Review* for December five cases of this kind are collected from German sources. Four proved fatal, and the necropsy showed the same condition in all—hæmorrhagic encephalitis. One recorded by Professor B. Fischer may be taken as an example. A healthy physician, aged 40 years, in the course of his professional work contracted a chancre on the septum nasi. There was a maculo-papular eruption. On March 28th, 1911, 0·4 gramme of salvarsan was injected intravenously. A slight rigor and several attacks of vomiting followed. In a few days the eruption faded and the primary sore rapidly healed. As a prophylactic against relapses he underwent a course of mercurial inunctions. Five days after its completion (on May 6th) 0·4 gramme of salvarsan was given intravenously. This was at first well borne, and after a day's rest in bed the physician saw his patients, but during the night he became ill, and on the following morning was found by Professor Fischer partially conscious. When roused he tried to answer questions, but with little success. There was constant movement of the upper part of the body. In the afternoon, after a fit of excitement, coma and Cheyne-Stokes respiration supervened, and in the evening there was opisthotonos. The temperature rose to 104° F., and death occurred at 5.15 A.M. on the following morning. The necropsy showed general parenchymatous degeneration of the organs and a fatty liver. The brain was diffluent and there was slight chronic leptomeningitis of the parietal and frontal regions. The pial vessels were distended. Microscopically, numerous punctiform hæmorrhages were seen around the minute vessels

[1] THE LANCET, Oct. 14th, 1911, p. 1085.
[2] THE LANCET, Nov. 4th, 1911, p. 1283.

of the basal ganglia and polynuclear leucocytes distending the perivascular spaces (hæmorrhagic encephalitis). A German case of fatal jaundice after the administration of salvarsan is also reported. Jaundice has been noted in several cases of the administration of the drug. At a meeting of the Royal Academy of Medicine in Ireland on Nov. 3rd Mr. H. Moore reported a case in which 0·5 gramme of salvarsan was injected intravenously in an early case of general paralysis in a man aged 25 years.[3] A severe reaction with rise of temperature to 103° followed. Six weeks later the injection was repeated and still severer reaction and death with paralytic symptoms followed. It is curious that most of the deaths have followed a second injection. This has led Professor Fischer to suggest that anaphylaxis may play a part. The point is important in connexion with the recent claim of some of the advocates of salvarsan that two injections are necessary to cure syphilis.

THE EXPLOSION AT AN OIL-CAKE MANUFACTORY.

THE inquest held at Liverpool upon the bodies of those killed in the explosion at Messrs. Bibby's oil-cake manufactory did not reveal any definitely ascertained cause for a disaster which caused the loss of 30 lives. The verdict of the jury was one of "Accidental death caused by dust explosion, the origin of which has not been clearly demonstrated." And they added to this, "Whilst we do not suggest that there is any blame to be attached to the management, we think that as the inquiry has demonstrated new dangers in dust special care should be taken with arrangements for ventilation and for the removal out of the danger zone of fine dust from the machinery." The evidence showed that in the making of feeding cakes for cattle at Messrs. Bibby's mills cereals and other ingredients were used which produced in the process of grinding a considerable quantity of dust, and also that it was recognised by those responsible that such dust was of a highly inflammable nature. In the preparation of rape seed for use benzine was employed in considerable quantities, but this process was not carried out in the part of the building where the fatal explosions originated. A disintegrator, known to the workmen as a "devil," working in a part of the building called by them the "devil's cellar," was used for pounding or breaking up materials for the cake, and explosions due to the ignition of the dust so caused were known to have taken place, but they had not before had any serious results. Machinery for the purpose of drawing away and collecting the dust was in use, but it was known that in spite of it some dust escaped into the air of the building. There was no mechanical ventilation, but large doors were kept open as freely as possible, and the windows were without glass. The first ignition of dust apparently took place in the "devil's cellar" and spread immediately to the other floors of the same building. To account for the ignition suggestions or conjectures were put forward, but no evidence of fact bearing directly upon the point was obtainable. According to the evidence of the firm's engineer, recent experiment showed that a flame such as that of a lighted match could have produced it, and the danger of this had been acknowledged by a rule forbidding workmen to smoke or to carry matches in the building. Only electric light was used, and every reasonable precaution was enforced. The engineer in his evidence, however, spoke of having found an unignited match on the day before the accident between a pair of electro-magnets, and he suggested that it might have been placed there by a lad in order that he might use it for smoking, but not have it on his person if searched. The same witness had suggestions to make as to how the explosion was actually caused. He described how he had found in the "devil's cellar" a large driving belt broken and an electric fuse gone. His suggestion as to this was that the breaking of the belt might have stirred up and driven into the air dust deposited upon beams and other resting places in its neighbourhood, and that the fusing of the electric wire, whether due to the breaking of the belt or not, had occurred at the same moment and ignited the dust. This, he explained, would account for the presence of a dangerous amount of dust in the air which should have been unusually free from it, because the explosion took place immediately after the dinner hour. Among other evidence given was that of Professor W. Collingwood Williams, who had found slight traces of naphtha in some of the cereals used by the firm, the presence of which might to some extent have contributed to the danger, and of Mr. Thomas Davies, consulting engineer, who spoke to the steps which might be taken to increase ventilation and reduce the amount of dust floating in the air. The verdict of the jury appears to be that which the evidence justified, and if it leaves the immediate cause of a very tragic disaster unaccounted for it should tend to prevent similar occurrences taking place in future by multiplying precautions the necessity for which has been so strikingly demonstrated. The dangerous character of dry, dusty, coal mines is well known and a method is in use which keeps the mine moist.

[3] THE LANCET, Dec. 2nd, 1911, p. 1556.

NATIONAL ASSOCIATION FOR THE PREVENTION OF CONSUMPTION.

THIS association (honorary secretary, Dr. J. J. Perkins, 20, Hanover-square, London, W.) is actively engaged in forming a library and bureau for the collection of all matters relating to pulmonary tuberculosis from every point of view, and in all countries. It is intended that such information shall be available not only to members of the medical profession but to the public at large. We are asked to state that valuable assistance would be rendered if medical officers of health, school medical officers, and medical superintendents or secretaries of hospitals, sanatoria, tuberculosis dispensaries, and open-air schools would kindly place the association on their distribution list in respect of annual reports or other documents bearing on the question of consumption. Books, pamphlets, and reprints of articles from physicians and social workers in general would also be gladly received.

CHINESE GREEN TEA.

A CORRESPONDENT in China has sent us the following note: "For many years past, owing to the demand of the foreign public for green tea, it has been the practice of some growers in China to colour the leaf artificially. After the leaves are roasted, which is done immediately on being gathered, they are rolled, coloured, and quickly dried. Formerly Prussian blue with gypsum was used, then indigo, and latterly aniline dyes have been employed. The Chinese themselves do not drink coloured teas, though they are fond of adding flavouring agents, such as jasmine and rose petals. The main demand for green teas came from America, and much consternation has arisen at the news just received in China that any tea containing artificial colouring matter will be refused admittance through the American Custom Houses. This year's crop, consisting of several million pounds, will therefore be thrown back on the Chinese exporters' hands, though an outlet may perhaps be found for it in Russia. Two millions pounds which were sent to San Francisco in a single shipment have already been refused entrance. The percentage of colouring matter is so slight and so innocuous that the objection is more of an academic one than a real

danger to the public health. The rejection is a result of the active steps which are at present being taken in America, mainly by Dr. Wiley, the State chemist, to enforce the observance of pure food laws in every detail. It is a pity, however, that longer notice had not been given by the United States Government of its intention, as the injunction coming at this time will involve many Chinese growers in loss. The various tea guilds here are quite ready to prepare their teas in future without colouring matter. The demand for 'country green' tea in America originated in the liking for a certain kind of leaf with a soft greenish-tinted down on its back which was thought to be an evidence of the freshness of the tea."

A POWERFUL appeal has been issued by the Lord Mayor of London, Sir Thomas Boor Crosby, on behalf of the Building Fund of the Royal Society of Medicine.

THE library of the Royal Society of Medicine will be closed from Saturday, Dec. 23rd, to Wednesday, Dec. 27th, both days inclusive.

THE HEALTH OF THE ARMY IN 1910.

THE report on the health of the army that has just been issued shows that the improvement which has been so marked a feature in these statistics during recent years is steadily continuing, and that the changes in medical administration, costly though they have been, have conduced to efficiency in greater proportion than the mere expenditure in money would lead one to expect.

Improved Health of the Army.

In the Director-General's introductory letter, summarising the chief points of interest, and in Abstract XXIX., it is seen that the admissions to hospital, the number of men constantly sick, and the deaths are the lowest on record; only in the number of men invalided is there a slight increase as compared with the previous year. The figures are ratios per 1000.

	Admissions.	Constantly sick.	Deaths.	Invalids.
1889–1898 ...	997·3 ...	59·85 ...	9·03 ...	15·36
1905–1909 ...	563·8 ...	33·11 ...	5·04 ...	11·61
1909	504·8 ...	28·86 ...	4·10 ..	8·65
1910	443·1 ...	25·38 ...	3·44 ...	9·11

The figures for the year under review, when compared with those of the preceding quinquennium, and still more with the decennial ratios before the South African war, show that the improvement is neither slight nor transitory.

It may be of interest to contrast this result with the expenditure on medical services. For the ten years before the war, 1889–1899, the army estimates for total effective services averaged about £16,000,000 or £17,000,000 and the medical vote a little under £300,000; since the war, 1904–1910, the annual army vote has amounted to some £24,000,000 or £25 000,000, and the medical vote has approximated £450,000—that is, the total military expenditure and the expenditure under the medical vote have each in round figures risen about 50 per cent. It may be granted that the medical services have had their share in the increased outlay during the last ten years. What is there to show for this? The admissions to hospital in 1910 are considerably less than half what they were on an average in the decennium before the war (1889–1898); the number of men constantly ineffective by being sick in hospital is somewhat less than half, and the number of deaths not much more than one-third, of the corresponding numbers in the earlier period, while the number lost to the service by invaliding in this last year is not more than 59·4 per cent. of the former wastage. If the medical services have cost half as much again in the recent period as they did before 1900, the result of the expenditure has been more than a doubling of the efficiency, as shown by a halving of the sickness, and a still greater reduction in the mortality in the army.

The total force, amounting to 215,796 warrant and non-commissioned officers and men, may be divided into three groups from a medico-statistical point of view: the troops serving in the United Kingdom, who form about one half of this number (viz., 108,614); the army of India (72,491); and the remainder serving throughout the rest of the empire (34,691).

Ratios per 1000.

	Admissions.	Constantly sick.	Deaths.	Invalids.
	United Kingdom.			
1889–1898 ...	712·5 ...	41·14 ...	4·32 ...	16·98
1905–1909 ...	428·3 ...	24·34 ...	2·84 ...	14·01
1910	346·0 ...	20·42 ...	2·42 ...	11·07
	India.			
1889–1898 ...	1464·7 ...	89·61 ...	16·43 ...	14·78
1905–1909 ...	802·5 ...	47·26 ...	9·08 ...	8·99
1910	576·5 ...	31·93 ...	4·77 ...	6·51
	Colonies.			
1889–1898 ...	869·6 ...	54·37 ...	8·44 ...	11·24
1905–1909 ...	505·8 ...	32·29 ...	4·70 ...	8·56
1910	457·3 ...	27·21 ...	4·21 ...	7·58

This marked and continuous improvement is the result, we conceive, of four factors: improved medical administration; advance in treatment, especially the great increase in operative procedure during recent years; the adoption of more scientific and more vigorous methods of prevention; and the employment of medical officers as medical inspectors of recruits, which has led to greater care in their selection.

Recruiting.

The number of recruits medically examined has been 45,671, a reduction of about 10 per cent. on the number examined in 1909, and no less than 25 per cent. less than those examined in 1908; the reasons suggested in the report as contributing to this diminution are emigration, revival of trade, and the existence of labour exchanges, which frequently obtain employment for men out of work who otherwise would enlist.

The ratio of rejections, 295·42 per 1000, is slightly less than for the previous year, and still lower than the decennial average. This, however, does not indicate any improvement in the physique of the men presenting themselves for enlistment, because, in the first place, the higher standards of height and chest measurement in force during 1909 have been abolished; and, secondly, there has been a slight increase in men discharged as medically unfit within three months' service. The great majority of the recruits were growing lads, many of them out of work and in poor condition; on the whole, however, the quality is considered to have been satisfactory. The lads will fill out in time, but will not be capable of doing the full work of a trained soldier for a year or two after enlistment. The chief causes of rejection have been, as usual, loss and decay of many teeth (56·95 per 1000 recruits examined), defective chest measurement (43·97), and heart disease (40·38). Defective vision (18·15) was practically the same as in the previous year, as was the disability from defective teeth; defective chest measurement was less frequent, also defective height and weight. This was not, however, due to improvement in the lads' physical condition, but to lowering of the standards to the normal recruiting requirements—viz. (for infantry), a height of 5 ft. 3 in., and a chest measurement of 33½ to 35 in., a range of chest expansion of 2 in. being required.

The condition of the teeth of the young adult working-class population is of considerable importance for the national welfare; the medical inspection of school children has now been carried out for some time, and improvement is to be looked for in the adult in the near future—perhaps it is too soon to expect to see any as yet; none is visible, at any rate, in the class of men and lads that present themselves for enlistment. A considerable sum is spent annually on the dental treatment of recruits, and whatever else it does for them, their first term of service, at any rate, ensures their possession of a set of teeth in decent condition.

The rejections for heart disease, 40·38 per 1000, were 7·32 per 1000 more than in the year preceding, and 17·41 per 1000 more than in the previous decennium; in addition, 1·84 per 1000 were rejected as unfit within three months of enlistment. The total number of men, presumably healthy in other respects, found to be unfit for the

not over-exacting work of the soldier was thus 1928 in the course of the year; the report states that any special cause for the increase was not apparent, except on the hypothesis of inferior physique generally, owing to reduction of the chest measurement standards demanded. We think this is a serious matter that needs careful inquiry with regard to the general question of physical degeneration in this country. Defective vision, 18·15 per 1000, caused much fewer rejections than the decennial average (32·09), the reason being that the vision test is now by Snellen's test types instead of by the dots formerly in use.

Of the total number of recruits finally approved during 1910—viz., 31,547—after deducting those under 18 years of age (2885), the average age was 19·6 years, the height was 66·3 in., the minimum and maximum chest measurements (average) were 33·4 in. and 35·8 in., the range of expansion 2·6 in., and the weight 128·8 lb. These figures are, within a very small fraction, all equal to those of the preceding decennium, and must be allowed to be, on the whole, satisfactory.

The system of physical training, introduced in 1906, is reported on favourably, though in some commands more instructors and smaller classes would be advantageous; no recruits have been discharged within three months of enlistment owing to any disability connected with the training system, either directly or indirectly.

Invaliding.

There are five principal causes of invaliding in the Army: diseases of the circulatory system, nervous, tuberculous and digestive diseases, and syphilis: all of these, except the tuberculous group, show a slight rise, and the total figure of 9·11 per 1000 is 0·46 above the ratio for 1909, though well below that for the quinquennium or any single preceding year. Until 1908, circulatory diseases had been in every year, except 1905, the chief cause for invaliding; this is now the third year in succession that they take second place, with a ratio of 1·56 per 1000; before 1905 the ratio had always been above 2·5 per 1000. The reduction appears therefore to be established, and although the report does not allude to this point, it may be suggested that alterations in methods of drill and in details of clothing and equipment have brought about the improvement. The fractional increases in nervous affections, which accounted for 1·63, in digestive diseases with 0·64, and in syphilis with 0·26 per 1000, are not of importance. Tuberculous affections (1·24 per 1000) remain year by year at about the same level. The total invaliding ratio, 9·11 per 1000, though fractionally above the unprecedentedly low figure of 8·65 in 1909, is now, we hope, established permanently at a low level.

HEALTH OF THE TROOPS IN THE UNITED KINGDOM.

Sickness, Deaths and Invaliding.

The admissions to hospital, number of men constantly sick, and the rates for deaths and invaliding have already been given above.

In the London District the admissions were 604 per 1000, the number constantly sick 36·9, and the invaliding 14·8; in the Western Command these ratios were 245, 13·3, and 8·9 respectively. On comparing the different arms of the service we find that the Household Cavalry have the highest admission rate (698 per 1000), and the Foot Guards the highest number constantly sick (34); the infantry of the line, on the other hand, have only 359 admissions per 1000 and 21·7 constantly sick. On comparison with the statistics for the preceding five years all branches of the service show an improvement in the number of admissions to hospital except the Household Cavalry; and all show a lessened inefficiency from sickness, again with the exception of the Household Cavalry, and to a very slight extent of the Royal Engineers. This excessive liability to illness on the part of the Life Guards and Horse Guards, as shown by an admission rate of 698 per 1000, compared with a rate of 482 for cavalry of the line (who have similar duties) and 496 for the Foot Guards (who serve in the same stations), is a matter for which some explanation seems desirable. It is noted that the Foot Guards have greatly improved their position compared with the other branches; their admissions have been 496 and their constantly sick 34 per 1000, as compared with 701 and 48·7, the ratios for the quinquennium.

The most fatal diseases amongst soldiers at home were pneumonia (0·27 death per 1000), tubercle of the lung (0·13), and valvular disease of the heart (0·11). The diseases causing most sickness were gonorrhœa, syphilis, and soft chancre, which together caused a constantly sick ratio of 6·48 out of the total 20·42 per 1000. This, however, is an improvement on the average for 1905–09, which was 7·10. The chief diseases causing invaliding were diseases of the nervous system (1·63), heart disease (1·43), and tubercle (1·40 per 1000); in each case there was a slight improvement on the quinquennial average. Diseases of the heart and circulatory system caused nearly as many deaths (0·34) as the quinquennial average (0·35), but led to less invaliding (1·78 compared with 2·69 per 1000); this indicates that heart-strain is now not a common accompaniment of the physical training of the soldier.

Venereal diseases caused 31·8 per cent. of the total inefficiency through sickness. The greatest proportion of admissions occurred, as always, in the London District, 137 per 1000; in the Western District there were only 44 per 1000. Sore throat and tonsillitis were much less prevalent during 1910 than of late years, the admission ratio having been only 26·3, as compared with a quinquennial average of 44·4 per 1000. Admissions were most numerous in the London District, as usual. None of the specific infectious diseases were prevalent in 1910, except influenza to a slight extent, causing 13·2 admissions per 1000, but it was not of a severe type. This section of the report concludes with the observation that the figures of sickness, mortality, and invaliding are now so low that any very considerable reduction in the future can hardly be anticipated.

Vaccination.

Out of the total 32,179 recruits found on inspection fit for service, 56·8 per 1000 had neither marks of vaccination nor of small-pox. The proportion of unprotected persons is increasing year by year. In the five years, 1891–95, it averaged 27·7, in 1896–1900 it was 34, in 1901–05 it was 39·3; in the last five years the ratios have risen rapidly from 35·9 in 1906 to 50·6 in 1909, and 56·8 in the past year. No danger accrues to the army because every recruit that needs it is either vaccinated or revaccinated; but if these figures are to be taken as generally applicable to the young adult male population they indicate that a large amount of inflammable material is accumulating throughout the country.

Sanitation.

Instruction in sanitation is now being carried out by lectures and demonstrations in all commands; the sanitary officers give lectures at the largest stations, and regimental officers instruct their men in elementary sanitation and personal hygiene; in the Territorial Force also series of lectures and practical demonstrations have been given at many centres. At the Aldershot School of Army Sanitation 858 officers and men passed through during the year, a considerable increase on any previous year's work. At the staff college also lectures are given by a specially appointed medical officer on the rôle of the medical service in war, the gain to efficiency from sanitation and disease-prevention being specially emphasised. There can be no doubt that a general knowledge of sanitary principles and an appreciation of the importance of such matters from a military point of view are becoming diffused throughout the army; in the Southern Command, where the greatest number of troops were collected together in camps, the Principal Medical Officer reported that the spread of knowledge and the combined efforts of all ranks had resulted in the maintenance of a high standard of sanitation in the various camps and barracks. This spread of knowledge and cordial coöperation have been an important factor in the production of a standard of health throughout the army that has never been previously reached.

Experimental work has been carried on at the Army Medical College and the Aldershot School of Sanitation in connexion with the supply of water to troops in the field; a clarifying drum has been under trial, with the use of alum as a preliminary both to the Griffith system of purification by heat, and to the filtration of the regulation water-cart; it has been found that 80 to 90 per cent. of contained micro-organisms can be removed in this way, thereby largely increasing the efficiency of the subsequent process. A new steam disinfector has been designed by the officer in charge of the Aldershot school; while at the Army Medical College a good deal of work has been done in relation to the food

requirements of soldiers, a second experimental march having been carried out during the year under the direction of the professor of hygiene.

Infectious Diseases.

The reduction in the incidence of infectious disease has continued, all the principal headings showing a smaller number of admissions. There have been only 43 cases of enteric fever, and measles, scarlet fever, and influenza have prevailed but slightly; for diphtheria there have been 57 admissions—nearly the same as in 1909. The only deaths in this group have been 4 from enteric fever and 1 from influenza. Under this last-named heading are recorded 1432 admissions. It is perhaps doubtful whether all were due to the specific micro-organism. Enteric fever caused only 43 admissions, giving a ratio of 0·4 per 1000, compared with a ratio of 0·6 for the preceding quinquennium. Most cases were sporadic; 6 occurred in the Belfast district, of which 3 were considered to have been infected at McGilligan Camp, where a possible chronic carrier was detected. Tonsillitis and sore-throat showed a great reduction; there were 26·3 admissions per 1000, compared with 44·4 in the preceding quinquennium. The progressive improvement in venereal sickness continues most satisfactorily; the admissions were 65·5 per 1000, compared with the quinquennial average of 76; and the constant inefficiency was 6·48 instead of 7·10. The reduction does not appear to be very considerable at first sight, but it may be recalled that for the decennium 1891–1900 the admission ratio was 143·7, and for the five years 1886–1890 it was 207·6; therefore the admissions are less than one-third of what they were 20 years ago. This must be considered to be most satisfactory.

Structural Improvements.

Structural improvements are constantly in progress in barracks, quarters, and hospitals, but no work of any magnitude has been completed during the year; the new cavalry barracks at Redford, near Edinburgh, are in progress, and new infantry barracks will shortly be commenced. The new block at Victoria Barracks, Windsor, is practically completed. The old Royal Artillery barracks at Woolwich are to be reconstructed, a work, we should think, already long overdue. Some years ago it was decided to provide pedestal flush down closets for troops instead of the old-fashioned trough latrines; it was feared that these new closets would suffer from rough usage and want of care or intelligence on the part of the men. It is satisfactory to learn that such has not been the case; this indicates a general improvement in the character and intelligence of the private soldier, which is indeed abundantly evident in many other ways, and is a hopeful sign of the times.

The Mediterranean Area.

The stations in the Mediterranean Command are Gibraltar, Malta, Cyprus, and Egypt. No troops appear to have been quartered in Crete during 1910.

At *Gibraltar* the strength of the garrison was 3652, the admissions to hospital were 402·2 per 1000, the number constantly sick 31·45, and the death-rate 3·29; the death-rate was lower, but admissions and constantly sick rather higher than the quinquennial average. The increase in sickness has been due to minor ailments, chiefly venereal disease. There were 12 admissions for enteric fever, which of late has not been much in evidence; the cases occurred sporadically during the hot weather, and no cause could be traced, though unwashed vegetables and fruit and ice-creams were suspected. In eight of the cases pure cultures of B. typhosus were recovered from the blood early in the disease, leading to an early diagnosis and the speedy adoption of preventive measures. Two cases of Mediterranean fever occurred in January, the last of the outbreak due to goats' milk of the year before. The increase in venereal disease over the preceding year, 434 admissions compared with 304, was possibly connected with the presence of foreign warships. A mild outbreak of food poisoning occurred in November, ascribed to tinned salmon. Of 63 men who partook of the salmon made up into rissoles for breakfast, 40 were affected about noon, and of these 23 were admitted to hospital with vomiting, diarrhœa, colic, and slight collapse; these symptoms and the mode of onset point to a toxin rather than a bacterial infection. No tins of salmon of the same kind were found to be at all amiss, and the cooks noted nothing wrong in the tins that had been used. The incident is of interest, because the use of tinned salmon is universal, and the occurrence of illness after eating it in good condition almost unknown. It is probable, therefore, that some damaged condition was overlooked. Improvements have been carried out in barracks by the provision of wash-down "latrines" (? closets) in place of trough latrines, and the Horsfall destructors have worked well.

In *Malta*, where the strength averaged 6769, the troops have had a slightly higher admission rate than in the previous year; but the number of men constantly sick has been almost exactly the same, and the death-rate and invaliding show a marked improvement. When the figures are compared with those for the preceding quinquennium the improvement is seen to be still more satisfactory, the admissions having been 400·1, compared with 489·2; the constantly sick 24·44, compared with 32·36; and the deaths 2·81, compared with 4·26 per 1000. The invalids sent home have numbered only 8·42 per 1000, in marked contrast with 30·26 for 1905–09, the latter high figure depending chiefly on the Mediterranean fever prevalence of 1905 and 1906. In 1909 there was one admission for this disease; in 1910 not a single case occurred, except in the person of a young officer who had just arrived, and who drank milk unboiled, probably that of the goat. *En revanche* there were 47 cases of enteric fever amongst the troops, a much greater prevalence than in any year since 1905. Nearly all these cases occurred in January and February, in the form of a sharp outbreak, amounting in all to 61 attacks, distributed between officers, women, and children, as well as among the troops, and causing six deaths. No information is given as to locality of the epidemic, nor as to its circumstances, except that it was due to the water-supply, which was the same as that supplied to the civil population; as to this it is said that alterations "are under consideration" with a view to its protection. Paratyphoid fever caused seven admissions, all from the same barracks, and said to have been due to eating grapes. Under general diseases in Group C appears a new heading, Sandfly Fever, the fever due to an invisible virus disseminated by Phlebotomus pappatasii; 124 admissions are recorded; for comparison with previous years this entry must be combined with pyrexia of uncertain origin, for which there were 26 admissions; this total of 150 cases, giving a ratio of 22·1 per 1000, is less than half the prevalence in 1909, and little more than a quarter of that for the quinquennium (79·1). Although the affection is not serious, during that period it ranked third in causing inefficiency through sickness. Formaldehyde spray has been found useful in keeping down the sand-flies, a nuisance for which some parts of Malta have been notorious. A case of kala-azar is recorded, the first known to have become infected in Malta. We are glad to learn that the old Valetta Hospital has been converted into a reception station, that a new isolation hospital has been completed on the top of the ramparts at Cottonera, and that the building of a new hospital in a healthy and airy situation at Imtarfa is under consideration; also that new barracks are under construction at Tigne, which will reduce the number of men living in casemates. Last year we ventured to predict that now that "Malta fever" has been abolished in fact and in name, and that sanitation has improved so greatly, the island would regain most of its old popularity as a winter resort. From the health returns of 1910, however, when enteric fever is said to have been caused by pollution of the public drinking water-supply, we fear this opinion was too optimistic. It is to be hoped that the public health authority has already taken steps to safeguard the catchment area.

Egypt.—The average strength was 5592. The admissions were 551·3 per 1000, the constantly sick 36·82, and the death-rate 4·65, all these ratios being lower than for the preceding year except the last, which showed a fractional increase. All ratios, however, were lower than those for the preceding quinquennium. There were 12 cases of enteric fever, all sporadic, and occurring at wide intervals of time. No cause is assigned. There were 115 admissions for sandfly fever. Venereal diseases declined from 168 per 1000 admissions in the quinquennium to 128 per 1000 in 1910. The use of saponified cresol for latrines and urinals has given every satisfaction as a fly deterrent. This is thought to have caused much of the decline in enteric fever.

South Africa.

The force in South Africa, which had been largely reduced in 1909, was still further diminished in 1910 to a strength of 10,871. The health of the troops on the whole has slightly

improved, though the total admission ratio of 386·7 is rather higher than that of the preceding year, on account of an outbreak of scabies, causing 549 admissions. There were 30 admissions for enteric fever, giving a ratio of 2·8 per 1000, and a constantly sick ratio of 0·46, both being great improvements on 9·9 and 1·91, the corresponding quenquennial ratios. The largest number of cases at any one station occurred at Roberts' Heights, Pretoria, where there were 17 cases; but it is mentioned that only 7 could be demonstrated to be due to B. typhosus; 8 were due to atypical forms of the typho-colon group. No source of infection was traced. Admissions for malaria (23·9 per 1000) were double the quinquennial average, due to recurrent cases in units arrived from India; there were no fresh infections. An outbreak of scabies occurred, causing 549 admissions, or a ratio of 50·5 per 1000. Nearly all were from one regiment, transferred from Rangoon, the disease having rapidly spread under the conditions of life on board ship. An occasional outbreak of scabies or scurvy is useful as an antidote to a too optimistic view of ourselves or our environment. "Influenza" caused 126 admissions, a great increase over the previous year; 44 occurred at Potchefstroom, and are reported to have resembled sandfly fever, but "no sandflies exist in the neighbourhood." Most of the men had served in India, and a malarial origin was suspected, but no malarial parasites were found. At Pietermaritzburg most of the cases of influenza showed a scarlet fever rash. No sanitary measures of any great importance were undertaken in the Union, owing to uncertainty as to the future distribution of the troops.

India.

The thoughts of most of us during the last week or two have been turned to our Eastern Empire, and on reading graphic descriptions of oriental splendour and magnificent ceremonial, picturesque crowds, the magnificent appearance of the troops, Indian no less than British, the enthusiasm of everyone while one pageant succeeds another day after day in brilliant sunshine, many of us have been inclined to envy our fellow-countrymen dwelling in that pleasant land, far away from London fogs, where December, so far from being "drear-nighted," as it appeared to John Keats, affords perhaps the most brilliant and perfect climate imaginable. The weather conditions are, of course, not equally delightful all the year round; the sun is too powerful during some months of the year, and when it rains for three days without a break there is monotony as well as excess of moisture in the dwelling. The formerly prevailing idea of the "deadly climate" of such and such a place in the tropics is, however, now pretty well exploded. No climate is deadly; no climate is even unhealthy, if by climate we understand the conditions of weather, temperature, barometric conditions, rainfall, and so on. The diseases that were formerly called "climatic" are now known (in almost every case) to be due to some specific living cause, the development and activity of which may depend on climatic conditions, and therefore be greater in one climate than another; but the specific causes are not necessarily present even in the hottest climate, and even if they are present they can be destroyed by taking appropriate action.

The average strength of the European force serving in India was 72,491, a slight increase over that of the previous year. The health statistics, which in 1909 showed a marked advance on all previous returns, have in this last year again improved most noticeably. The admissions were 576·5, the constantly sick 31·93, and the deaths 4·66 per 1000, the corresponding figures for 1905–09 having been 802·5, 47·26, and 9·08. The invaliding ratio has come down to 7·75 per 1000, that for the preceding quinquennium having been 19·92. The marked improvement to which attention was drawn in the report for the previous year has been more than maintained in 1910. European troops now serving in India can enjoy a degree of good health undreamt of a generation ago.

The cause of the greatest number of admissions to hospital has been malaria (132 per 1000 strength), with which may be coupled sandfly fever (7·1), and pyrexia of uncertain origin (37·7). Venereal diseases caused 58·9, and the group of digestive diseases caused 52·5 admissions per 1000. In each instance the number of cases of illness has been less than the quinquennial average. The greatest inefficiency through sickness was due to the group of venereal diseases, for which 7·79 per 1000 were constantly sick in hospital; for fevers the inefficiency was 5·64, and for digestive diseases 2·56 per 1000. The diseases that were most fatal were enteric fever (causing 0·62 deaths per 1000), inflammation of the liver (0·52), diseases of the heart and aneurysm (0·44), tubercle (0·29), pneumonia (0·25), and dysentery (0·25). In each instance, both of inefficiency through sickness and of mortality ratio, there has been a marked reduction, except in the case of death-rate from tubercle, which remains practically the same as for the five-year average.

There remains to be mentioned enteric fever. In the preceding quinquennium, 1905 to 1909, the admissions averaged 13·7 per 1000, the numbers constantly sick 2·79, and the deaths 2·66; and in the decennium 1895–1904 the admissions averaged 22·3, the constantly sick 3·31, and the deaths 5·62. In the year 1910 the admissions were 4·1 per 1000, the number constantly sick 0·91, and the death-rate 0·62 per 1000. This is a result that ten years ago could hardly have been hoped for, still less expected. The report states that there have been no definite outbreaks of true enteric fever during the year, though isolated cases have occurred, scattered over a large number of stations. The 2nd Worcestershire Regiment at Jhansi had 21 cases, with 6 deaths; this was the largest number of cases in any one unit during the year. At Sialkot the admission ratio for enteric fever was 15·1 per 1000, at Kamptee 14·4, at Fyzabad 14·2, at Jhansi 13·1, and at Kirkee 12·0. No other station had an enteric incidence running into double figures. During 1910 an attempt has been made to differentiate paratyphoid fever from true enteric, though in the statistical returns both are included under the latter designation. Of the total 335 cases returned as enteric, 39 were definitely diagnosed, with undoubted isolation of B. paratyphosus A or B, as paratyphoid fever; 36 of these were cases of infection by the A bacillus; one case was fatal. A noticeable feature of the epidemic history of typhoid fever during the year has been the absence of any direct evidence to show that drinking water, milk, or indeed any article of food had been the cause of the disease. There had been much to suggest dissemination by carriers, especially undetected cases, but, on the other hand, there has been a remarkable freedom from attack amongst attendants on the sick. Inoculation has been carried out extensively during the year. On Dec. 31st, 1910, a census was taken and 81·7 per cent. of British troops were found to have been inoculated. The enteric fever convalescent depôts at Naini Tal and Wellington have done excellent work; 239 men were received at the former, where 6 chronic carriers were detected, and 81 at the latter, with detection of 3 carriers. It is hoped that before long accommodation will be afforded at these depôts for officers, women, and children.

Malaria, with 132 per 1000 admissions, was much less prevalent than in 1909 (when they numbered 202·8). The report does not pronounce definitely what was the cause of the improvement, but inclines to the view that it was the result of a lessened heritage of infection from the previous year, of the vigorous anti-malarial measures that had been taken in cantonments, and of the prophylactic administration of quinine. This last measure has been carried out systematically, but the injection of quinine salts, either subcutaneous or intramuscular, has been abandoned. Unfortunately a death occurred from tetanus following on subcutaneous injection. The use of mosquito nets by the troops is increasing. We share the regret expressed that owing to financial considerations the authorities have not seen their way to provide them at the expense of the State. As the value of this simple measure of fever prevention has been fully demonstrated, we consider that both on general grounds and on grounds of true financial economy the troops should be provided with mosquito nets at malarious stations, and made to use them. Sandfly fever caused 512 admissions, with no deaths; it prevailed at Nowshera, Attock, and Multan. Venereal disease has decreased generally; it still prevails much more extensively at Secunderabad, Poona, and Lucknow, and in Burma than elsewhere.

With regard to sanitary matters, we are glad to learn that a new type of incinerator has been evolved which is much superior in efficiency to any hitherto in use, and that the disposal of urine in absorption pits near urinals is likely to be carried out with success. The establishment of sanitary sections—that is, bodies of sanitary police to carry out water purification, disinfection, &c.—has been sanctioned by Government, and should be a valuable measure of disease prevention.

The report on the Health of British Troops in India, contained in the Blue-book on the Health of the Army in 1910, is indeed an astonishing record of improvement. The betterment in health has taken place all round—there is less malarial fever, less venereal disease, less liver disease. But the most striking feature has been the reduction in enteric fever. In former times we have often noted the occurrence of severe outbreaks of this disease, which in one year (1898) was more fatal than all other causes taken together. It is even now more fatal than any other single disease, but both in its prevalence and in its severity it has been to a great extent robbed of its terrors. It is not now the dread of the young soldier or officer going out to India at the commencement of his military career, as was the case some years ago. This result has been attained by the exercise of much labour and skill on the part of our colleagues in the medical service of the army, supported by an enlightened appreciation by the Indian Government, which has backed up their efforts and accepted their recommendations in regard to sanitary reform. The recent establishment of convalescent depôts for enteric patients, and consequent isolation of possible carrier cases, has no doubt largely influenced the reduction in enteric prevalence. Prevention has been demonstrated to be better and cheaper than cure, and the recognition of this fact by the Government, and the energetic carrying out of the principle all over the country, have reduced the sickness to little more than one-third, and the mortality to even less than one-third, of what it was 15 to 20 years ago.

Smaller Stations.

Bermuda and Jamaica form the Atlantic sub-group. At the former station there has been some increase in sickness as compared with 1909, due apparently to the arrival of a fresh regiment. There has also been an increase in the death-rate over that of the quinquennium. In Jamaica there has been a decided improvement. Malaria was not so prevalent as in the previous year, though many cases again occurred during gun practice in the malarial neighbourhood of Fort Nugent in November; this is stated to have been a necessity. In West Africa the troops had to undergo a "bad fever year." The admissions for malaria were 1032 per 1000, compared with a quinquennial ratio of 628, but no cases were fatal. A death occurred from yellow fever, which is endemic at Freetown. Malaria unfortunately broke out at Tower Hill Barracks, which have hitherto been considered to be free from infection. Tins and bottles had been allowed to be dumped on War Department land in the immediate neighbourhood of the barracks. Many were found to contain mosquito larvæ. These cases of fever were clearly preventable and were not prevented. In Mauritius, where the health of the troops was on the whole satisfactory, 15 cases of enteric fever were admitted, 8 of which appeared to have contracted infection from a cook, whose blood agglutinated with B. typhosus in a 1 in 50 dilution. In South China there was a considerable increase in the admissions for malaria at Hong-Kong, partly owing to the proximity of a nullah teeming with anopheline larvæ, and partly to an infected Chinese village. Both in North China and in the Straits Settlements the health of the troops showed an improvement over the statistics of previous years.

This report is admirably compiled, and contains a large amount of information interesting to all engaged in public health matters, as well as to those members of the profession who are in one way or another connected with the services of the Crown.

BEQUESTS TO BIRMINGHAM CHARITIES.—Several Birmingham institutions benefit under the will of the late Mr. John Roderick, a well-known auctioneer and surveyor—viz., the General Hospital £50,000, the Queen's Hospital £10,000, the Birmingham General Dispensary £1000, and the Skin and Urinary Hospital £1000. After the payment of sundry other legacies amounting to £70,900 the residue of the estate, which is estimated at £362,022, is left, as to half to the General Hospital, as to a quarter to the Queen's Hospital, and as to a quarter to the Birmingham General Dispensary. Mr. Roderick, who was in his eighty-first year, had been for many years a member of the board of management of the General Hospital; three beds in the hospital have been endowed at various times in memory of brothers of Mr. Roderick.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

A MEETING of the Governors and General Council of King Edward's Hospital Fund for London, for the purpose of awarding grants to the hospitals, convalescent homes, and consumption sanatoriums, was held on Dec. 11th at St. James's Palace. The Speaker of the House of Commons, the Right Honourable JAMES LOWTHER, was in the chair, and those present included the Duke of Norfolk, Lord Revelstoke, the President of the Metropolitan Hospital Sunday Fund (the Right Hon. the Lord Mayor), the President of the Hospital Saturday Fund, the Governor of the Bank of England (Mr. A. C. Cole), the President of the Royal College of Surgeons of England (Mr. R. J. Godlee), Sir W. S. Church, Sir Henry Burdett, Sir Horace Marshall, Sir Cooper Perry, Sir John Craggs, Dr. Edwin Freshfield, Sir T. Vezey Strong, Sir Joseph Dimsdale, Mr. Albert G. Sandeman, Mr. John G. Griffiths, and Sir Savile Crossley and Mr. Frederick M. Fry (honorary secretaries of the Fund).

In the absence of Lord Rothschild (honorary treasurer) Lord REVELSTOKE reported that the amount received by the Fund for general purposes to Dec. 8th, after payment of expenses, was £176,745 0*s.* 3*d.*

Sir HENRY BURDETT stated that the League of Mercy hoped this year that their contribution to the Fund and their distribution amongst the hospitals in the home counties would amount together to a sum of £20,000. He could not for the moment say exactly what sum.

The Chairman of the Distribution Committee (Sir WILLIAM CHURCH) read the report of that committee, which showed that the sum of £151,000 was in the hands of the committee with a view to distribution amongst the London hospitals, as against £150,000 in 1910. The committee reported that the number of hospitals applying for grants was 105, as against 106 last year. They add: "Among the institutions which do not appear in this year's list is St. George's Hospital, the governors of the hospital having withdrawn their application as a result of the decision of the Fund on the question of the amounts which could properly be paid to the medical school in respect of work done for the hospital. The grant of £2000 which was reserved last year lapses, the conditions attached to it by the council of the Fund not having been fulfilled." With regard to the applications received during the year from four out of the five throat, nose, and ear hospitals no detailed scheme of amalgamation had yet reached the stage at which a grant from the Fund could be recommended. Under the circumstances the committee advised that the total sums set aside or promised towards a general scheme of amalgamation should be increased to £20,000, and should remain at that figure pending an agreement upon a satisfactory scheme or schemes. The committee recommended that they should be empowered to draw upon this sum, in appropriate proportions, in the event of a general or partial amalgamation being brought to a satisfactory conclusion before the next distribution. The committee reported with satisfaction that the poor district of Kentish Town would shortly be provided with improved hospital accommodation by the rebuilding of the out-patient department of the amalgamated Hampstead and North-West London Hospitals. The sum of £5000 voted towards the removal of King's College Hospital to South London increased the total amount contributed by the Fund to this object to £42,000. The enlargement of the annual statistical report to cover practically all the hospitals applying for grants enabled the committee to extend the practice of drawing the attention of the hospitals concerned to cases where the excess of cost above the average seemed to call either for specific justification or for greater attention to economy.

Sir Savile Crossley then presented the list of awards, premising that the absence of a grant did not imply dissatisfaction with an institution. The following are among the chief awards:—

Belgrave Hospital, £1500 (£1000 to reduce building debt); Bolingbroke Hospital, £1400; Central London Ophthalmic Hospital, £1500 (to rebuilding in accordance with the scheme submitted to the Fund); Charing Cross Hospital, £4000 (£1000 to special appeal for reduction of debt); City of London Hospital for Diseases of the Chest, Victoria Park, £4000; City of London Lying-in Hospital, £1000 (£500 to reduce building debt); Dreadnought Hospital, £450 (£500 to reduce debt, and £500 to underpinning of Docks Branch); East London Hospital for

Children, £2000 (£500 to recent improvements in accordance with the scheme submitted to the Fund); Great Northern Central Hospital, £4000 (£1000 to reduce debt); Guy's Hospital, £6,500; Hampstead General Hospital, £4500 (£1650 on account of maintenance and rent, as agreed upon amalgamation with the North-West London Hospital, and £2750 to rebuilding the out-patient department in Kentish Town in accordance with scheme submitted to the Fund, on condition that the balance is raised by the hospital); Hospital for Consumption, Brompton (including Sanatorium at Frimley), £4000; Hospital for Epilepsy and Paralysis, £1500 (£1000 to extension in accordance with the scheme submitted to the Fund); Hospital for Sick Children, £3500 (£500 to reduce general fund debt); Hospital for Women, Soho-square, £1750 (£500 to reduction of mortgage on No. 4, Frith-street); King's College Hospital, £7000 (£5000 to removal fund); London Hospital, £12,000; London Lock Hospital £4500 (£500 to the Harrow-road Hospital, and £4000 to the rebuilding of Dean-street Hospital in accordance with the scheme submitted to the Fund); London Temperance Hospital, £1500; Metropolitan Hospital, £3500; Middlesex Hospital, £4000; Miller General Hospital for South-East London, £2750 (£2000 to extension in accordance with the scheme submitted to the Fund); Mount Vernon Hospital for Consumption (including Sanatorium at Northwood), £2500; National Hospital for the Paralysed and Epileptic, £1750; New Hospital for Women, £1500 (£750 to structural improvements in accordance with the scheme submitted to the Fund); Paddington Green Children's Hospital, £1250 (£750 to reconstruction of Out patient Department in accordance with the scheme submitted to the Fund); Prince of Wales's General Hospital, £4000 (£1500 to reduce debt; the committee consider that this hospital should receive more support from the public); Queen's Hospital for Children, £3500 (£1500 to reduce debt); Royal Eye Hospital, £1000 (£250 to reduce debt); Royal Free Hospital, £3000; Royal Hospital for Diseases of the Chest, City-road, £1500 (£250 to reduce debt); Royal London Ophthalmic Hospital, £2250; Royal National Orthopædic Hospital, £5000 (£3000 to reduce building debt); Royal Waterloo Hospital for Children and Women, £1750 (£250 to recent improvements); St. Mary's Hospital, £5500 (£1500 to reconstruction of casualty department in accordance with the scheme submitted to the Fund); St. Mary's Hospital for Women and Children, Plaistow, £1000 (£250 to roof garden for patients); Samaritan Free Hospital, £1750 (£750 to new nurses' home in accordance with the scheme submitted to the Fund); South Wimbledon, Merton, and District Cottage Hospital, £1000 (to the rebuilding of the hospital in accordance with the scheme submitted to the Fund); University College Hospital, £4000; Victoria Hospital for Children, £1250 (£250 to recent improvements); West Ham and East London Hospital, £2000; West London Hospital, £5000 (£2000 to reduce debt); Westminster Hospital, £3500.

The report of the Convalescent Homes Committee was read by Dr. FRESHFIELD, in the absence of the chairman, Mr. William Latham, K.C. It announced that the committee had received the sum of £6500 for distribution amongst convalescent homes and consumption sanatoriums. The amount distributed in 1910 was £5000. The committee adhered to their original policy of giving special consideration to the convalescent homes closely connected with London hospitals, and reported with satisfaction that the scheme for placing beds in country consumptive sanatoriums at the disposal of patients in London hospitals had proved satisfactory. The grants recommended for consumption sanatoriums amounted to £3500; those for convalescent homes to £3000. The awards were presented by Mr. Frederick M. Fry (honorary secretary).

The SPEAKER of the House of Commons, before moving the adoption of the reports and awards, read the following communication from the King:—

Emperor's Camp, India, 9th December, 1911, 2.45 P.M.

On the occasion of the Annual Meeting on Monday I wish to congratulate the Governors and Council of the Fund upon the satisfactory results achieved last year. I am glad to think that they can increase the annual distribution by £2500, indicating the continued support of the public and confidence in its efficient administration. I highly appreciate the generous and untiring work given to the Fund by the honorary secretaries and members of the various committees; and I take as ever the deepest interest in its welfare. GEORGE, R.I.

After expressing on behalf of those present deep appreciation of His Majesty's kind message he said the total this year for distribution was £157,500, representing an increase of £2500—£1000 in the amount distributed to hospitals and £1500 in the amount distributed to convalescent homes and comsumption sanatoriums. Among the receipts which had made possible this progress he mentioned first the increased annual subscription of 100 guineas with which Her Majesty the Queen had honoured the Fund. This, following upon the increase last year of His Majesty's subscription from £500 to £1000 and the subscription of £100 from H.R.H. the Prince of Wales, was yet another mark of the interest taken by the Royal Family in the Fund, and their recognition of the needs of the hospitals of London. His Majesty had also allocated to the Fund a share amounting to £2000, in the munificent Coronation gift of His Highness the Maharaja of Gwalior. The receipts again included an anonymous donation of £10,000, and the City Corporation had for the third time in succession voted an annual subscription of £500 for five years. The contribution of the League of Mercy continued to be one of the largest items in the list of receipts. He regretted the withdrawal of St. George's Hospital from the list of applicants, but the Fund was bound by the findings of Sir Edward Fry's Commission on the Financial Relations between Hospitals and Medical Schools. The scheme of the Convalescent Homes Committee for placing beds in consumption sanatoriums at the disposal of London hospitals had been very successful, and the result of the circular issued to the principal hospitals inviting expressions of opinion as to the probable effect of the National Insurance Bill upon their finances and the numbers of their patients had been published in the form of a short summary of opinions.

The Duke of NORFOLK seconded the motion, and the adoption of the reports was carried unanimously.

The CHAIRMAN then announced the intentions of the Governors to re-appoint for the year 1912 the whole of the existing members both of the council and of the committees.

On the motion of Sir HENRY BURDETT, seconded by Sir SAVILE CROSSLEY, a resolution was passed expressing the thanks of the council to Mr. Fry for his services as honorary secretary.

The LORD MAYOR proposed a vote of thanks to the Speaker of the House of Commons for presiding. The resolution was seconded by Mr. COLE and carried unanimously.

The SPEAKER having briefly acknowledged the vote of thanks, the proceedings then terminated.

ANNUAL REPORT OF THE MEDICAL OFFICER OF THE LOCAL GOVERNMENT BOARD.

III.

WE now proceed to notice the remainder of Dr. Newsholme's report, which deals with the work of the Board's medical department and also with certain special matters that have engaged the attention of the staff in the course of the year.[1]

Medical Inspections.

A considerable portion of the time of the medical staff is occupied in the inspection and regulation of vaccination, at least 13 of their number having been thus engaged during the year. But arrangements are in force for the performance of other preventive functions by the inspectors during their routine visits on vaccination duty. For example, the inspectors have instructions to make inquiries, and where necessary to give advice to local authorities and their officers as to sanitary circumstances generally, and especially as to the condition of dwelling-houses and of existing systems of refuse disposal. They also inform themselves as to local methods of dealing, by hospital isolation or otherwise, with tuberculous phthisis and other infectious diseases, and further as to local arrangements for the control of water- and milk-supplies.

Protection of Food-supply.

The food inspectors regularly supervise the local arrangements for the protection of the food-supply in port sanitary districts, and they occasionally hold inquiries respecting the administration of the Adulteration Acts, with especial reference to the efficiency of the measures locally taken to secure the wholesomeness and purity of food. Since the issue of the Board's regulations in 1907 the general improvement in the condition of the foods arriving at our ports has been maintained, and steps have been taken to inquire locally as to compliance with the Board's instructions relating to foreign meat. As the result of inspectorial visits to Belgium and Holland, it is reported that the measures there adopted by the authorities to comply with our requirements are satisfactory in every respect.

Several outbreaks of food poisoning were reported during the year. Dr. A. W. J. MacFadden, who has charge of this department, gives particulars of such occurrences at St. Helens, Carlisle, Gateshead, and elsewhere. He complains, however, that in the majority of cases the information was not received until so long after the occurrence of the mischief that the opportunity of effectively assisting local preventive measures had passed.

[1] Previous notices of this report appeared in THE LANCET of Nov. 25th, p. 1501, and Dec. 9th, p. 1649.

New Pathological Laboratory.

The Local Government Board is now equipped with a permanent pathological laboratory. The staff includes, in addition to the laboratory assistants, the director, Dr. A. Eastwood and Dr. F. Griffith, both of which officers had been engaged for several years on investigations for the Royal Commission on Tuberculosis. The laboratory was in full working order by the end of December, 1910, but hitherto the investigations undertaken have in the main been limited to tuberculosis. There is every reason to hope that under the direction of Dr. Eastwood and his colleague the newly equipped pathological laboratory will greatly increase the efficiency of the Board's medical department.

Government Lymph Establishment.

In the course of the 12 months ended in March last nearly half a million capillary tubes of glycerinated calf lymph were issued by the vaccine establishment to public vaccinators, and further, 26,000 tubes of lymph were issued to the navy, and 56,000 to the army, during the same period.

Extraneous Duties of Medical Staff.

In the course of the comments already made respecting the public health of 1910 we have alluded to much of the work of the Board's medical department, but the account of that work would be incomplete were omission made of the manifold duties for which the services of individual members of the staff have been requisitioned by other departments of the State. For example, the principal medical officer has served as a member of the General Medical Council, and in that capacity has taken part in revising the regulations for diplomas in public health. He has advised on public health questions referred to him by the Foreign Office and the Colonial Office, affecting this country's colonies and dependencies, and finally he has been consulted from time to time by the Privy Council Office and the Post Office on matters bearing on health questions. Dr. H. Franklin Parsons represented the Board at the meetings of the Committee of Advice on the Geological Survey. For several years past he has been engaged on an inquiry respecting hospital construction, and although he has retired from office arrangements have been made with him for the completion of that work. Dr. R. Bruce Low continued to serve on the Committee of the Advisory Board of the Army Medical Service. Dr. Theodore Thomson continued to act as representative of H.M. Government on the Committee of the International Office of Public Health. He has also continued to serve as a member of the Advisory Medical and Sanitary Committee for Tropical Africa appointed by the Secretary of State for the Colonies. Dr. G. S. Buchanan, assistant medical officer and chief inspector of foods to the Board, has made some inquiries under the Midwives Act, which have been utilised in the section of the present report dealing with puerperal sepsis. Dr. L. W. Darra Mair has acted as chairman of the Departmental Committee on Sanitary Matters, and Dr. R. Farrar has visited China as the representative of H.M. Government on the International Commission of medical experts to investigate the plague in Manchuria.

Tenure of Office by Medical Officers of Health.

Among special subjects dealt with in the report we note that the conditions of appointment (including their tenure of office) of medical officers of health have been in some respects improved by the issue of a new Order of the Local Government Board. Power is now given for the appointment by any sanitary authority of a medical officer of health *without limit of time*. In such cases the officer cannot be dismissed without consent of the central authority. Another section of the Order provides that an officer appointed for a specified time will after the expiration of that time continue to hold office indefinitely, *but he is still subject to three months' notice*, and no further approval by the Local Government Board is necessary. Dr. Newsholme predicts that inasmuch as the practice of annual reappointments will, by virtue of this clause, almost entirely cease, the medical officers will be able to perform their duties without the impending fear that they may not secure a majority of votes of the local council when reappointment becomes due. Whether or not this prediction is well founded future events must determine. We ourselves are strongly averse to the granting of uncontrolled powers of dismissal to a local authority, except in the rare instances in which there is practically no danger of abuse.

County Medical Officers of Health.

A General Order has recently been issued prescribing the duties of county medical officers of health. Briefly put, they include all the duties already devolving upon district medical officers of health, together with some others of a supervisory character. In particular, the county medical officer is required to inform himself of all influences affecting the public health in every part of the county, to consult with the district medical officers, and to present an annual report. This Order, by securing due supervision of local sanitary work by the county medical officer, will give additional guarantee of its accomplishment without fear or favour; and the reports of these officers will, it is hoped, give year by year a fairly complete conspectus of the health and sanitary condition of every administrative county. County medical officers are now generally debarred from private practice, and enjoy a fair measure of independence.

Improvement of Vital Statistics.

As a result of conference between the Board's medical officer and the Registrar-General, certain far-reaching improvements will shortly be made in the collection and presentation of statistics of sickness and mortality by which the returns of the local health officer will be coördinated with those of the General Register Office. New skeleton tables for the use of medical officers of health have already been distributed by the Board and will be used in the compilation of their reports for the year 1911 onwards. Under a new regulation the Board requires from every medical officer of health a weekly statement of the cases of infectious disease notified in his district. In return for this each contributing medical officer receives from the Board a summary of the returns of all the sanitary districts in England and Wales. By the help of these returns medical officers of health everywhere receive prompt and important warning respecting the danger of importation of infection from other districts, whilst the return to the central office enables a closer watch than heretofore to be kept of the prevalence of such diseases and the general health conditions of the country.

Auxiliary Scientific Investigations.

For several years past the Local Government Board has received a Parliamentary grant in aid of scientific investigations, and with the help of this useful work has been accomplished during the year under review. We may refer, as of special importance, to the work on the etiology of epidemic diarrhœa, conducted independently, but on similar lines, by Dr. C. J. Lewis, Dr. Sheila Ross, Dr. R. A. O'Brien, and Dr. J. Orr. An investigation into the possible conveyance of infection by flies has been carried out under the supervision of Dr. Monckton Copeman, in coöperation with Professor G. H. F. Nuttall, of Cambridge, and an account of a laborious investigation into the bacterial contents of the air of sewers and drains has been contributed by Dr. F. W. Andrewes. We have already noticed the special study of Dr. A. C. Inman on secondary infection in tuberculosis, a brief account of which appears in an appendix to the present report.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MEETING OF COUNCIL.

AN ordinary meeting of the Council was held on Dec. 14th, Mr. RICKMAN J. GODLEE, the President, being in the chair.

A report was read from the Board of Examiners in Anatomy and Physiology for the Fellowship stating that at the examination recently concluded 127 candidates were examined, and that 32 were approved and 95 rejected.

A report was read from the Court of Examiners, and in accordance therewith it was resolved to issue Diplomas of the Fellowship to 30 successful candidates.

In accordance with a report from the Board of Examiners in Dental Surgery, it was resolved to issue Diplomas in Dental Surgery to 44 successful candidates.

The PRESIDENT reported the delivery of the Bradshaw lecture on Some Points in Heredity by Mr. R. Clement Lucas (see p. 1755 of our present issue). The best thanks of the Council were given to Mr. Lucas for his lecture, and he was requested to publish it.

Mr. C. B. Lockwood was elected a member of the Museum Committee in the vacancy occasioned by Mr. Godlee, the President having become an *ex-officio* member of the committee.

Mr. Edmund Owen was re-elected a member of the Court of the University of Liverpool for a period of three years.

A report from the committee on the annual report of the Council was considered, and it was resolved to take no action in reference to the Resolutions 3 and 4 carried at the annual meeting of Fellows and Members in November.

A protest was read against the National Insurance Bill from the wives of over 800 duly registered medical men of Manchester, Liverpool, Oldham, Blackburn, and other towns and places in England and Wales.

In response to a request from Sir William S. Church, chairman of the Brown Sanatory Committee of the University of London, the Council resolved to allow Mr. Twort, the superintendent of the Brown Institution, to give his course of five lectures at the College in January.

A letter was read from Sir James F. Goodhart, offering to present to the College a marble plaque of Mr. Edward Cock, President of the College in 1869. The offer was accepted with thanks.

A letter was read from Sir Henry Morris reporting the proceedings of the General Medical Council at their late session, and the best thanks of the Council were given to Sir Henry Morris for his services as a representative of the College on the General Medical Council.

Public Health.

REPORTS OF SCHOOL MEDICAL OFFICERS.

Borough of Macclesfield.—Mr. J. H. Marsh's report lays stress on those elementary questions which are so insistent in school work. It is noted that "without exception the boys at each age period whose teeth are classed as very bad are the lowest weights of all the boys examined." Cleanliness, too, is dealt with at length. "How can children," the report reads, "coming from a home where the only water-tap is in a yard common to several houses, and where all the hot water needed for bathing has to be got from a pan on the kitchen fire, be kept decently clean?" And the question is asked, "Are not school baths a logical necessity to compulsory school attendance?" Mr. Marsh answers that the installation of a system of shower baths would "immensely improve the general well-being, discipline, and self-respect of the children." And while agreeing that in some cases parental neglect is responsible for the children's filthy condition, he points out that as in most working-class homes in Macclesfield facilities do not exist for a thorough-going hot bath, "the systematic and regular bathing of a family of children by a tired mother with few facilities for obtaining a sufficient supply of hot water is a great tax on human endurance." Treatment of defects found is another question considered, and special arrangements for dental treatment of all children at 7 years are recommended. Vision defects are already dealt with by the prescription of spectacles by the ophthalmic medical inspector. Out of 61 nose and throat cases followed up by the nurses at the end of the year 28 had received some kind of medical attention, but in 33 nothing had been done. Mr. Marsh says that inspection without treatment merely means a waste of money and the accumulation of reports, and urges the establishment of a school clinic to treat nose and throat, dental, ear, and vision cases. It is interesting to notice in connexion with the feeding of school children that this was done in Macclesfield at six schools on the advice of the medical officer, and the children were also selected for feeding by him. A mid-morning lunch was given—bread-and-butter and milk, porridge and treacle and milk, or half milk cocoa and bread-and-dripping or bread-and-margarine and jam. "The children were quite unaccustomed to such good plain food, and appeared to have been brought up either on tea and bread-and-butter or expensive and innutritious delicacies."

Durham County Council.—Dr. T. Eustace Hill's report, while taking a broad sweep and being conceived from a standpoint which completely surveys the ground, yet finds room for all needed precise detail and for three special reports by medical inspectors which are of particular value. Dr. Alice M. Burn's report on "Clothing in Relation to Physique and Physical Exercise" makes some striking statements and some highly practical suggestions which it is much to be hoped will be taken up by the education authority. Dr. Burn states "that 70 per cent. of the girls in our elementary schools are physically victimised to their clothes.....The infant of 5 years just entering school already only too often bears the stigma of the binder in the laterally compressed thorax and the pigeon chest. The small school girl is now encompassed round about by quilted staybands of a semi-rigid type, thin string-like tape supports cut into the little shoulders, the costal margin is gripped by the returning tie tapes which pass from back to front, the whole garment expressive of constraint and compression. Lung expansion and chest movement are chronically restricted, the forward droop of the shoulders with its associated hollow clavicles and prominent abdomen, is initiated and encouraged, while the whole body axis is thrown into the worst possible position for practically all the physiological processes of respiration, digestion, and elimination. .....The real needs of the developing growing body, crying out at every natural movement for space and freedom to expand, are utterly ignored or denied." This is pretty strong condemnation, but every school medical officer must feel that it is justified and will be glad to have some of the deficiencies exactly defined. Most school medical officers also will have "removed or unfastened ten different items [of clothing] before reaching the poor little cramped chest beneath," and Dr. Burn states that she and the school nurse "have constantly remarked the better chest development and the good general physique of many of the so-called neglected cases." This latter observation may apply to country areas, but does not appear applicable to towns. A very practicable suggestion in order to further ideas of rational clothing is that the Durham Coöperative Stores (from which in this county practically every home purchases) should be induced to stock "school children's and infants' garments of a rational and hygienic type." This is merely, according to Dr. Burn, a matter of planning and cutting, and she proposes, if the education committee considers the matter momentous enough, "to submit a set of clothing similar to what I have introduced elsewhere and undertake any preliminary inquiries as to material, cost, output, &c." In illustration of the deficiencies of ordinary clothing, it is mentioned that at one school, where an enthusiastic teacher was conducting physical drill on the admirable new Board of Education syllabus lines, "the movements designed to develop waist and back muscles had all to be cut out, not to mention many of the leg exercises." Dr. Burn concludes her valuable paper by a plea for the introduction of morris-dancing and for instruction for sixth and seventh standard girls in personal hygiene and home management. Dr. J. G. W. Boleyn, in a report on the Effect of Dental Caries and Oral Sepsis upon Children's Health, gives a useful list of foods which cause and foods which prevent caries, and notes the greater relative prevalence of this condition amongst "better-class" children. Two further useful reports are added—on Amelioration, by Dr. Victoria E. M. Bennett, and on Personal Cleanliness, by Dr. Elizabeth N. Niel.

Borough of Newport.—The third annual report of the infantile health centre committee is issued from the health department of the Newport corporation and contains some interesting reading for educationists and school medical officers. An early paragraph states that "the results of the examinations of school children prove that one must search for the causes [of physical defects] at a still earlier age in the majority of cases." The committee which reports has been endeavouring to cope with the causes at an earlier period by providing "schools for mothers," where not only instruction in hygiene is provided but extra nutriment for nursing mothers in the form of milk. Help with rational clothing is given and a maternity club established. But the committee concludes that "a striking circumstance, however, continually presents itself to all who labour for the welfare of the infants of the nation. It is the intimate relation between child mortality and poverty." It is much to be hoped that the sphere of influence of this committee may extend and that many imitators may be found in other places.

VITAL STATISTICS.

VITAL STATISTICS OF LONDON DURING NOVEMBER, 1911.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases, it

* Including membranous croup. † The death-rates are corrected for variations in sex- and age-constitution of the populations of the several boroughs, the population of England and Wales being taken as the standard. ‡ Deaths from "typhus fever" and "other continued fevers" are not now distinguished in the Registrar-General's weekly returns; these two columns are therefore omitted from the Table.

appears that the number of persons reported to be suffering from one or other of the ten diseases specified in the table was equal to an annual rate of 7·8 per 1000 of the population, estimated at 4,522,628 persons in the middle of the year. In the three preceding months the rates were 4·4, 6·9, and 8·5 per 1000 respectively. The lowest rates last month were recorded in Paddington, Kensington, Hammersmith, Chelsea, the City of Westminster, Holborn, and the City of London; and the highest rates in Fulham, Hackney, Finsbury, Deptford, Greenwich, Lewisham, and Woolwich. The prevalence of scarlet fever showed a marked decline from that recorded in the previous month; among the several metropolitan boroughs the greatest proportional prevalence of this disease occurred in St. Marylebone, Hackney, Lambeth, Wandsworth, Camberwell, Deptford, and Woolwich. The Metropolitan Asylums Hospitals contained 2103 scarlet fever patients at the end of last month, against 1324, 1656, and 2152 at the end of the three preceding months; the weekly admissions averaged 254, against 261 and 317 in the two preceding months. Diphtheria was slightly more prevalent than it had been in the preceding month; this disease was proportionally most prevalent in Fulham, St. Pancras, Finsbury, Greenwich, Lewisham, and Woolwich. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals, which had been 720, 892, and 1143 at the end of the three preceding months, had risen to 1327 at the end of last month; the weekly admissions averaged 180, against 138 and 168 in the two preceding months. The prevalence of enteric fever showed a considerable decrease from that recorded in either of the two preceding months; the greatest proportional prevalence of this disease occurred in Fulham, Islington, Holborn, Finsbury, and Lambeth. There were 85 enteric fever patients under treatment in the Metropolitan Asylums Hospitals at the end of last month, against 56, 155, and 160 at the end of the three preceding months; the weekly admissions averaged 9, against 39 and 23 in the two preceding months. Erysipelas was proportionally most prevalent in Stoke Newington, Hackney, Finsbury, Shoreditch, Bethnal Green, Stepney, Southwark, and Bermondsey. The 40 cases of puerperal fever notified during the month included 5 in Southwark, 5 in Lambeth, 4 in Hackney, 4 in Stepney, 4 in Wandsworth, 3 in Fulham, and 3 in St. Pancras. Of the 20 cases of poliomyelitis notified, 4 belonged to Lambeth, 3 to Shoreditch, and 2 each to Hackney, Stepney, Poplar, and Battersea; and 2 of the 6 cases notified as cerebro-spinal meningitis belonged to Finsbury.

The mortality statistics in the table relate to the deaths of persons actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the several boroughs in which the deceased persons had previously resided; the death-rates from all causes are further corrected for variations in the sex- and age-constitution of the populations of the several boroughs. During the five weeks ending Dec. 2nd the deaths of 5827 London residents were registered, equal to an annual rate of 14·1 per 1000; in the three preceding months the rates had been 18·9, 16·8, and 15·1 per 1000 respectively. The death-rates last month ranged from 10·7 in Lewisham, 11·0 in Kensington, 11·1 in Wandsworth, 11·2 in Hampstead, 11·3 in Woolwich, and 11·8 in the City of London, to 16·7 in Bermondsey, 16·8 in Bethnal Green, 17·0 in Poplar, 17·1 in Holborn, 17·7 in Finsbury, and 19·0 in Southwark. The 5827 deaths from all causes included 52 from measles, 19 from scarlet fever, 78 from diphtheria, 32 from whooping-cough, 20 from enteric fever, and 149 among children under two years of age from diarrhœa and enteritis. No death from any of these diseases was recorded last month in the City of London; among the metropolitan boroughs they caused the lowest death-rates in Kensington, Islington, Stoke Newington, Hackney, and Woolwich, and the highest rates in Hammersmith, Chelsea, Finsbury, Bethnal Green, Southwark, Wandsworth, Greenwich, Poplar, and Deptford. The 52 deaths from measles were less than one-third of the corrected average number in the corresponding period of the five preceding years; of these 52 deaths, 20 belonged to Deptford, 9 to Southwark, 7 to Camberwell, 4 to Greenwich, 3 to Battersea, and 2 to Bermondsey. The 19 fatal cases of scarlet fever were 28 fewer than the corrected average, and included 3 in Finsbury, 2 in St. Marylebone, 2 in Islington, 2 in Shoreditch, 2 in Poplar, and 2 in Wandsworth. The 78 deaths from diphtheria were slightly below the corrected average; this disease was proportionally most fatal in Fulham, Chelsea, the City of Westminster, Hampstead, and Poplar. The 32 fatal cases of whooping-cough were 26 below the corrected average number, and included 5 in Poplar, 4 in Wandsworth, and 3 in Lambeth. The 20 deaths referred to enteric fever showed a decline of 8 from the corrected average number; of these 20 deaths 3 belonged to Hammersmith, 3 to Lambeth, and 2 each to Fulham, St. Pancras, Poplar, and Wandsworth. The 149 deaths from diarrhœa and enteritis among children under two years of age were less than half the number in the previous month; the greatest proportional mortality from this cause was recorded in Hammersmith, Chelsea, Finsbury, Bethnal Green, Bermondsey, and Wandsworth. In conclusion, it may be stated that the aggregate mortality in London last month from the principal infectious diseases (excluding diarrhœa) was 47 per cent. below the average.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

IN accordance with the provisions of Order in Council of April 1st, 1881, Fleet-Surgeon Hubert William Austin Burke has been placed on the Retired List at his own request.

The following appointments have been notified:—Fleet-Surgeon: G. T. Bishop to Malta Hospital. Staff-Surgeons: D. V. Lowndes to the *Pembroke*, for R.N. Barracks; and R. R. Horley, L. M. Morris, and G. H. M. Mills to the *Victory*, additional, for disposal. Surgeons: A. D. C. Cummins to the *Victory*, for R.N. Barracks; W. R. Harrison to the *Victory*, additional, for disposal; G. Moir to the *Vivid*, additional, for disposal; and G. T. Verry to Haslar Hospital.

ARMY MEDICAL SERVICE.

Surgeon-General Sir Francis W. Trevor, K.C.S.I., C.B., K.H.S., is retained supernumerary to the establishment, under the provisions of Articles 92 and 472 Royal Warrant for Pay and Promotion, 1909 (dated Dec. 11th, 1911). Colonel Thomas M. Corker to be Surgeon-General, vice Sir F. W. Trevor, K.C.S.I., C.B., K.H.S. (dated Dec. 11th, 1911). Colonel (temporary Surgeon-General) William Babtie, V.C., C.M.G., to be Surgeon-General to complete establishment (dated Dec. 11th, 1911). Lieutenant-Colonel James M. Irwin, from the Royal Army Medical Corps, to be Colonel, vice T. M. Corker (dated Dec. 11th, 1911).

ROYAL ARMY MEDICAL CORPS.

Lieutenant Arthur J. O. Wigmore resigns his commission (dated Dec. 16th, 1911).

Lieutenant-Colonel G. G. Adams, commanding the Military Hospital at Colaba, Bombay, has been selected for the higher rate of pay under Article 317 of the Royal Warrant. Lieutenant-Colonel T. McCulloch has arrived home, tour-expired, from India, and has been appointed in charge of the Medical Divisions of the Royal Victoria Hospital at Netley. Lieutenant-Colonel M. J. Sexton, lately in medical charge of the Military Hospital at Arbor Hill, Dublin, has embarked for a tour of service in South Africa. Lieutenant-Colonel J. Donaldson, in charge of the infectious diseases hospital at Aldershot, has been detailed by the War Office for a tour of service in India, and on arrival will be posted for duty in the Second (Rawal Pindi) Division. Lieutenant-Colonel T. Daly has been selected to hold Medical Charge of the Station Hospital at Peshawar. Lieutenant-Colonel M. P. C. Holt, D.S.O., honorary surgeon to the H.E. the Viceroy of India, has been appointed to command the Station Hospital at Kasauli. H.E. the Commander-in-Chief in India has been pleased to grant an extension of the command of the Station Hospital at Lucknow to Lieutenant-Colonel H. N. Thompson, D.S.O., honorary surgeon to H.E. the Viceroy. Major G. M. Goldsmith has been selected for appointment to command the Station Hospital at Lebong. Major T. H. J. C. Goodwin, D.S.O., on completion of his Indian tour of service, has been appointed to the Southern Command. Major F. Harvey, from Devonport, has taken up duty at Bodmin. Major L. N. Lloyd, D.S.O., on completion of his tenure of appointment as adjutant of the Royal Army Medical Corps School of Instruction at London, has been posted for duty in the

Western Command. Major F. J. C. Heffernan, from the London District, has taken up duty with the Fifth (Mhow) Division in India. Major S. de C. O'Grady has been transferred from the Military Hospital at Khartoum to Cairo. Major H. E. Staddon, from Shorncliffe, has been appointed to the Military Hospital at Dover. Major R. H. Lloyd, lately adjutant of the Royal Army Medical School of Instruction at Exeter, has embarked for a tour of service in India, and on arrival will be posted to the Third (Lahore) Division. Major E. P. Sewell, from Belfast, has taken up duty in Ceylon. Major J. V. Forest, in medical charge of the troops at Kasr-el-Nil, Cairo, has been transferred for duty at the Military Hospital, Khartoum. Major J. D. McCarthy, from Multan, has taken up duty at Rawal Pindi. Captain E. V. Aylen has been transferred from Nowshera to Barian. Captain J. M. H. Conway, from the Royal Infirmary, Phœnix Park, Dublin, has taken up duty as Adjutant of the Royal Army Medical Corps School of Instruction at Leeds in succession to Major H. S. Roch. Captain F. M. Parry, from Maidstone, has embarked for a tour of service in Mauritius. Captain J. W. S. Seccombe has arrived home for duty from Nasirabad. His Honour the Lieutenant-Governor of the United Provinces in India has been pleased to appoint Captain T. Scatchard to hold Civil Medical Charge of Ranikhet in addition to his military duties in succession to Major W. G. Beyts. Captain S. M. W. Meadows has taken over Charge of the Military Families Hospital at Tidworth Park, Salisbury Plain. Captain F. W. W. Dawson, from Dublin, has embarked for a tour of service with the Northern Army in India. Captain T. J. Potter, at present employed in the London District on medical recruiting duty, has been placed under orders for a tour of service in Egypt. Captain H. G. Sherren, from Colaba, and Captain C. F. White, from Jhansi, have been detailed for duty on board the troopship s.s. *Dongola*, leaving Bombay for Southampton on Dec. 28th. Captain A. W. Sampey, on relief by Lieutenant-Colonel F. W. H. Burton, in charge of the Military Hospital at Warley, has been granted six weeks' leave of absence prior to embarkation for a tour of service in India. Captain J. Powell has arrived home on leave of absence from Egypt. Lieutenant H. Gall, from Dagshai, has taken up duty at Simla. Lieutenant A. S. M. Winder, from the Curragh, and Lieutenant M. White, from Bordon, have embarked for a tour of service in India. Lieutenant L. F. K. Way, from Cosham, has been transferred for duty at the Military Hospital, Hilsea. Lieutenant H. F. Joynt, from Hounslow, has embarked for a tour of service in South Africa. Lieutenant G. P. Taylor has been transferred from Irvine to Glasgow for duty at the Military Hospital. Lieutenant S. S. Dykes, on the closing of the Training Camp at Barry, has been posted to Aberdeen. Lieutenant S. W. Kyle, from Jubbulpore, has been appointed to the Station Hospital at Jhansi. Lieutenant A. W. Byrne, from Dalhousie, has taken up duty at Lahore Military Hospital.

INDIAN MEDICAL SERVICE.

The King has approved of the confirmation of the commissions of the following Lieutenants on probation with effect from July 29th, 1911:—Edward Slade Goss and Percival Sandys Connellan.

The King has approved of the retirement of Lieutenant-Colonel D. G. Crawford (dated Dec. 5th, 1911).

H.E. the Viceroy and Governor-General of India has been pleased to appoint Colonel J. Smith, officiating principal medical officer of the Secunderabad Brigade, to be an Honorary Surgeon on His Excellency's personal staff, in succession to Surgeon-General P. H. Benson, retired. Lieutenant-Colonel W. R. Edwards has arrived home on leave of absence from India. Major F. F. Elwes has been appointed Surgeon to H.E. the Governor of Madras. Major A. M. Fleming, civil surgeon at Raipur, has been granted furlough on medical certificate home from India for one year. Major H. J. Walton has been selected for appointment as Civil Surgeon at Saharanpur. The Chief Commissioner of the Central Provinces has appointed Captain M. F. Reaney, civil surgeon at Wardha, to the Executive and Medical Charge of the Wardha District Jail. On relief by Major T. G. N. Stokes, of the office of the Sanitary Commissioner of the Central Provinces, Major W. H. Kenrick has been placed on special duty in connexion with the investigation and prevention of malarial fevers in the Central Provinces. Major J. W. F. Rait, Bengal Presidency, has been permitted by the Right Hon. the Secretary of State for India to extend his leave of absence by four months. Major A. A. Gibbs has been appointed Medical Storekeeper to the Government of India at Lahore, in succession to Lieutenant-Colonel P. W. O'Gorman, who has vacated the appointment. Surgeon-Captain W. A. Murray, in medical charge of the Assam-Bengal Railway Volunteer Rifles, has been granted leave of absence home from India for one year and three months by the General Officer commanding the Assam Brigade. Captain A. W. Overbeck-Wright, officiating superintendent of the Central Prison at Agra, has been appointed to officiate as Superintendent of the Lunatic Asylum at Agra, in succession to Major A. W. R. Cochrane, granted leave of absence. Captain C. F. Marr, medical storekeeper to the Government of India at Bombay, on relief by Major F. E. Swinton, returning from furlough, has been detailed to rejoin his regiment. Captain W. Jeudwine has been appointed to officiate as Civil Surgeon of Simla, West, during the absence on deputation to Delhi of Lieutenant-Colonel C. Duer. Captain J. W. McCay, Bengal Presidency, has been permitted to extend his leave of absence home from India for one month on the recommendation of a medical board. Captain A. W. Howlett, whose services have been placed temporarily at the disposal of the Government of the United Provinces, has been appointed to officiate as Superintendent of the Central Prison at Agra. Captain N. S. Wells, on return from leave, has been appointed Civil Surgeon at Ghazipur. Captain D. Munro has been granted an extension of leave for three months by the Right Hon. the Secretary of State for India. Captain H. C. Keates has relinquished charge of the duties of superintendent of the Jullundur District Jail. Captain E. T. Harris has been granted four months' extension of his leave of absence. Captain G. D. Franklin has taken up duty as Agency Surgeon at Gilgit on return from leave. The services of Captain E. C. C. Maunsell have been placed temporarily at the disposal of the Government of India. Captain J. Cunningham has been selected for appointment to the Bacteriological Department. Captain N. S. Sodhi has taken up duty as Plague Medical Officer in the Gurgaon District.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Captain and Honorary Major William V. Sinclair (Honorary Lieutenant in the Army) resigns his commission, with permission to retain his rank and wear the prescribed uniform (dated Dec. 16th, 1911).

TERRITORIAL FORCE.

Royal Army Medical Corps.

2nd East Lancashire Field Ambulance, Royal Army Medical Corps: Lieutenant William F. Munro to be Captain (dated Sept. 23rd, 1911).

1st Wessex Field Ambulance, Royal Army Medical Corps:—The undermentioned officers to be Captains (dated Nov. 5th, 1911): Lieutenant Thomas Duncan, Lieutenant George P. D. Hawker, Lieutenant John Miller, and Lieutenant Richard Eager.

Supernumerary for Service with the Officers Training Corps.—The undermentioned officers from the Unattached List for the Territorial Force are appointed, with rank and precedence as on the Unattached List, for service with the medical unit of the University of London Contingent, Senior Division, Officers Training Corps (dated Dec. 16th, 1911): Captain Archibald Montague Henry Gray, Lieutenant (Provisional Captain) Robert Davies-Colley, Lieutenant (Provisional Captain) Alfred Edward Johnson, Lieutenant John Charlton Briscoe, Lieutenant Thomas Bramley Layton, Lieutenant Gordon Clunes McKay Mathison, and Lieutenant William Victor Corbett.

THE MILITARY SURGEON.

In the December issue of the *Military Surgeon* Major Paul F. Straub, of the General Staff, U.S. Army, Sanitary Inspector, Manœuvre Division, gives an interesting account of the working of the Medical Department of the division at San Antonio, Texas, under the new field service regulations. The Medical Department was made responsible for the sanitary service of the division, and was given by the commanding general the necessary authority and means for carrying it on. The result was that after the lapse of four months the sick rate of the division is reported as never having exceeded half the average sick rate at the military

posts. General orders defined and prescribed the power and authority of the chief surgeon and the sanitary inspector, and dealt with the water-supply, regimental surgeons, disposal of wastes, the sale of foods and drinks in camps, and the control of sanitary squads. Illustrations are given of a type of garbage incinerator which was finally developed as the result of experiment, and was found very efficient.

Correspondence.

"Audi alteram partem."

THE NATIONAL INSURANCE ACT.

To the Editor of THE LANCET.

SIR,—It is desirable that the action of the medical profession with regard to the National Insurance Act should be based on a clear enunciation of just principles, and on a recognition of undeniable facts. The Act is founded on a system of contract medical practice.

Now it cannot be denied that (1) contract practice involves an undertaking by the practitioner to perform what it is certain that he will not always be able to perform; (2) contract practice destroys the relation of mutual confidence between patient and practitioner, and introduces an opposition of interests between them; (3) under contract practice no patient will ever be satisfied with the amount of attention which he receives from his doctor, however conscientious and diligent that doctor may be; (4) under contract practice the medical man is certain to be grossly overworked, to be subject to unreasonable calls (and at unreasonable hours) for the most trifling ailments, and to be constantly liable to dismissal for failing to perform what it will be impossible for him to perform.

If these facts are undeniable, is it not clearly the duty of every member of the profession to refuse to work under the Act *so long as it is administered on a basis of contract?*

I am, Sir, yours faithfully,

Dec. 19th, 1911. DAVID B. LEES, M.D., F.R.C.P.

To the Editor of THE LANCET.

SIR,—The amount of unpaid labour imposed on medical men by the services that they are expected to give on the committees of this Act does not appear to have received the attention that their onerous nature demands. The Insurance (Health) Committees are to consist of from 40 to 80 members, their meetings will necessarily be protracted, frequent in number, and often distant from the residence of the medical men serving on them, so that much time and expense will be involved in attendance.

This, however, would be only a portion of the *corvée* since much more work would be entailed by interviews and correspondence with medical co-workers and attendance at the meetings of the local panel or committee. This work will also involve considerable friction and worry, increased by the knowledge that the work is utterly useless and hopeless, since they will always be in a minority on the Insurance Committees of 1 to 16.

The time occupied in service on a Health Committee could scarcely occupy less than ten working days of eight hours per annum and might easily be more. These committees, allowing for the county subdivisions, will number at least five hundred and the number of medical men employed on them must exceed a thousand. The extent of the medical *corvée* can be easily estimated. The Insurance Committees are, so far as the profession is concerned, a sham. The Friendly societies will dominate them completely and the profession will be handed over without power of resistance to the tender mercies of bodies whose "sweating" proclivities are well known. If the medical profession accepts the *corvée* imposed on it its members will be reduced practically to a state of socialistic serfdom.

I am, Sir, yours faithfully,

Queen Anne-street, W., Dec. 18th, 1911. HENRY RAYNER.

To the Editor of THE LANCET.

SIR,—The Chancellor of the Exchequer has stated that payment per visit is an impossibility under the present Insurance Bill. The logical conclusions to be drawn are: (1) the Government is dependent for the success of the Bill upon the *charity* of the medical profession—which ruins the Bill as a sound financial proposition; (2) the Government is deliberately *sweating* the medical profession—a disgrace to the originators of the Bill and an insult to the profession.

The "six cardinal points" of the British Medical Association *were* loyally accepted even by those of us who were not members, but in view of the way in which the Asssociation has been flouted I feel that the profession should now stand firm and demand *payment for work done*, and nothing less. The attitude of the profession has been hitherto very passive, but the apathy of its leaders is far from creditable. Does the General Medical Council mean to do nothing? Can it without protest allow the profession to be sweated? Is the charity of the profession to be farmed out by the State for profit without some intervention from the General Medical Council, or does it allow the State to do what it forbids to a commercial enterprise? Let us stop the huckstering and bargaining that have gone on and remember the dignity of our profession.

Payment for work done—that and nothing else—should be our watchword. Cannot this matter be taken in hand at once by some influential organisation? I am confident that it would meet with the entire support of the profession.

I am, Sir, yours faithfully,

Carlisle, Dec. 18th, 1911. RICHARD SEDGWICK, M.D. Cantab.

To the Editor of THE LANCET.

SIR,—Can you or any of your readers inform me why the British Medical Association in its six points insists on a wage-limit? Does it cost more to attend a man earning £2 2*s.* a week than a man sitting on the next stool earning only £2? Is there any logical basis for fixing any wage-limit, unless we propose to continue the semi-charitable methods of medical attendance that at present characterise club practice? If the pay fixed is *adequate* I cannot see that a wage-limit is needed.

The British Medical Association would have been better advised if they had faced the question of adequate pay in the first instance. If they had said 8*s.* 6*d.* per annum, to include drugs and dressings (not appliances)—in fact, the terms now paid for Post Office employees—they would have had practically all the medical men engaged in industrial practice behind them, and I honestly think the Government would have yielded to these terms. If any general practitioner agrees with me that an endeavour should now be made to secure these terms from the Commissioners I should be glad if he would send me a postcard.

I am, Sir, yours faithfully,

CHARLES F. SEVILLE, M.B. Lond.

Oulton, Leeds, Dec. 18th, 1911.

To the Editor of THE LANCET.

SIR,—I have seen nothing during this controversy as to the attitude that consultants will take, now that the Bill has passed, towards those members of the profession who may be willing to work under the Act in its present form.

In common with many other practitioners, I should be interested to learn if the consultants will be willing to meet them as usual. Is there any sort of authoritative body to speak for consultants, or will any senior man among them give his opinion?—I am, Sir, yours faithfully,

FRANK G. WALLACE.

Earl's Court-road, London, S.W., Dec. 16th, 1911.

To the Editor of THE LANCET.

SIR,—Dr. Luard, I think, says everything that can be said in favour of retention of our time-honoured system of payment by fee, and has thought of two or three fresh things to say against the system I am advocating—that of payment by premium *per capita*. Several of his points are well thought out and clearly put, and I will essay to meet them later on. He fails, however, to approach my two main standpoints. I will repeat them. 1. In the face of a constantly falling sickness rate, payment by fee inevitably means a declining income. I assert that every income

derived from, say, 1000 private clients to-day is much less than it was ten years ago, and is still declining. (It has required an increase of 200 in that time to keep my own income steady.) How are we, then, going to meet this decline? He proposes no remedy. There is no remedy but the system I advocate, unless we are turned into State medical officers. 2. Payment *per capita* on an adequate premium is more remunerative than payment by fee for work done. A thousand clients paying anything you like *per capita* per annum will yield more income than 1000 private clients of the same wage or salary or income class. I say "anything you like" without hesitation, because where there is a low club premium one may take it there will also prevail a low scale of fees per visit. Payment *per capita* is adaptable to all ranks of the community, and when one has gained a thorough grasp of the elementary principles of insurance one will see that this method is founded on a scientific basis. A considerable number of doctors and most of the public have no clear comprehension of the principles that underlie insurance. In illustration of this charge let me quote Dr. Luard: "What value will he place on services obtained for 4*s*. a year? He will value them just at four shillings' worth." If Dr. Luard goes to a club patient down with pneumonia, with the idea in his head that he is only being paid 4*s*. for his attendance on this patient, he is making a serious mistake. It is a mistaken idea that affects seriously the whole of his conduct of the case. With this idea in his head he naturally feels he is in the position of one who is giving a lot for next to nothing; that he is being exploited, imposed upon, sweated, and cheated; that "he need not give more than value for the money"; that "his sense of honour does not compel him to do more than earn his money." Club patients often imagine this also. Now, that the patient only pays 4*s*. per annum is true, but the service rendered to the individual is paid for by the combined premiums of all the club members.

It is owing to forgetting this fact that club work has been bespattered with every abusive epithet in the language. "Rural Practitioner's" letter last week will enlighten many as to the astonishingly small amount of work there is to do for the 4*s*. or 6*s*. *per capita* per annum. I am not protected as that practitioner is by anonymity, or I could give details that would endanger my very existence as club doctor. Dr. Luard should remember that the sum total of the members' premiums constitute the club salary which pays for all the visits he makes throughout the year to club patients. Many club members never degenerate into patients, but they are "covered" all the time. For 20 years and more I have paid large premiums to our medical sickness society and have not had a day's sick pay, but I have been "covered"! Is it "unethical" for this society to take all this money from me without rendering me any services? Is it wicked or unjust to receive premiums year after year from club members who are foolish enough never to call upon my services? Do I feel aggrieved? Have not I and they been "covered" all the time we have not been ill?

Once it is recognised that we get paid as much for all our year's visits to club patients as we do for our year's visits to private cases, opposition to the system must collapse. With free choice of doctor and under the Act, for instance, Nos. 1, 2, 4, and 5 of Dr. John Dunlop's objections in last week's issue at once fall to the ground; only No. 3 remains standing. Once it is recognised, we should realise that the club patient has hitherto not been treated with justice—he is entitled to all that a private patient expects and gets from his doctor "as measured by our visits and their results." If any one doubts whether his own practice would show results like those recently discovered in mine and related in my previous letters, I beg him to investigate. It is a very simple piece of work and can be done in half an hour. One should ascertain the number of club members and the total amount received from them in a year. Then from the ledger one should count all the names therein and now living, adding names of members of each household, and not forgetting to count in the names of those one knows would come to us if they ever became ill (there are many such in every practice), and add up the total—this will give the number of one's *private clients*. Finally, ascertain one's income from *private patients*. Thus we have: so many club *members* pay so much salary; so many private *clients* yield so much income. Any difference there may be I am confident in believing will be found to be to the advantage of club practice. And it is a difference in its favour that is growing greater every year. In figures I may put it thus: 500 or *x* club members will yield more income than 500 or *x* private clients of the same class.

"Any transaction in which the payment is a known fixed sum and the work an unknown variable quantity stamps itself as a gamble," says Dr. Luard, having in mind, of course, this pernicious payment *per capita*. This statement would be perfectly true, not only of insurance for medical attendance, but also of insurance against burglary, or fire, or broken windows, but for one slight flaw in the premiss. He describes the work as an unknown variable quantity. Let me ask him if it is not true that birth-rates and death-rates and sickness-rates, &c., vary so slightly year by year that actuaries are enabled to base their calculations for premiums for insurance against all sorts of risks, on the recurrence of an average. How could insurance companies do business if they had nothing but a gambling guess to work on? Does he not know that the number of sick days that any club will have to find sick pay for next year can be calculated—I do not say to a certainty—but to a marvellous approach to actuality?

But let us look at the sentence again. "Any transaction in which the payment is a known fixed sum and the work an unknown variable quantity stamps itself as a gamble." In medical practice a confinement which entails "work of an unknown variable quantity" is paid for by a known fixed sum—it may be months ago the lady's inquiry was answered as to fee. Here is gambling, indeed. Work variable? There are no two confinements alike. I may, indeed, say that no two consecutive visits on a morning's round are alike. They are all dissimilar, variable, and unlike. Dr. Luard may "give substantially the same time and care to all cases," but are these the only factors of a visit? What of distance, quantity, period of day or night, professional acumen called forth, &c. Doesn't he discriminate at all? Dr. Luard thinks "that from reasons of expense private clients only call us when they need." And do they always pay us for the call and do we only call when they need us? A friend of mine was once called to see a child with measles at the house of one of his wealthiest patients. He wrote a prescription, gave full directions as to diet, &c., and on leaving was told by the mother that he need not call again unless he was called, and that if he should be needed she would call him. As he was not called he naturally concluded he was not needed, so of course he did not call, but a few weeks afterwards he heard from his chemist that the whole family of eight children had heroically struggled through measles on that prescription and those directions.

There will be "enormously enhanced work," Dr. Luard tells us, if payment is to be on the *per capita* system. Is, then, the nation, on the Act coming into operation, suddenly going to take on fearsome unknown diseases, to pick up germs we have never dreamt of, to hurt itself in quantities we have never known before? Or is the nation going to set about raising its birth-rate? To quote Dr. Luard again, but lastly, "When one considers the quality of work turned out by overworked people I think it will be admitted," &c. This is, of course, a jibe at the sort of work a club doctor does when he is in the thick of influenza. It is, however, quite easy to twist this argument to face the case of the fashionable West-End physicians, who, I gather from my morning's paper, "are exceedingly busy now that winter colds have descended upon us." I trust the quality of the work of our *confrères* of the West-End does not deserve the description Dr. Luard applies "to the work of over-worked people."

I am commiserated for wasting my efforts on "a deservedly lost cause." Is it going too far to say of "payment by fee for work done" so ably defended by my opponent that it was seen to sicken on the day the first medical officer of health was appointed, and that it has been failing visibly ever since, and that the attending physicians have now given up hope of its recovery.—I am, Sir, yours faithfully,

West Mersea, Colchester, Dec. 17th, 1911. B. HALL.

To the Editor of THE LANCET.

SIR,—Black and white do not differ more from each other than do the extreme opinions as to what would be a fair rate of payment for the medical men, by means of whom the Insurance Bill would have to be worked. If one could find some guide as to what has been fixed as a fair rate by the

Government in the past in some like circumstances, it would be possible to form some basis upon which to build. Luckily there is one such arrangement in being, and there has been for many years. The surgeons appointed to attend the coastguards are paid at the rate of half-a-crown an attendance, and a shilling a mile is allowed for mileage. This is modest enough payment to suit the most fastidious of economists. Surely no one would suggest that the visit of a skilled medical man is to be valued at less than half-a-crown, or that for mileage he should be content with less than a livery stable keeper. It will no doubt at once be argued by the promoters of the Bill that the funds to be forthcoming will not allow of anything like such a rate of payment, and that we must take a capitation fee of so much. In plain English this means that the amount per visit statistically worked out from the amount of the proposed capitation fees would come to much less than the half-a-crown together with the amount for mileage, or, in other words, that a great nation means to force medical attendance on its citizens by exploiting the services of its medical men like any East-end employer of sweated labour.

But a Government department has seen fit to institute this very rate of payment for attendance on one of the most healthy classes of man to be found in the country. We should be required to attend the halt, the lame, and the blind; and the whole average of the health would be much lower than that of the coastguards.

If the authorities persist that the money cannot be forthcoming in that amount, what is that to us? We never asked for any interference with our professional relations, nor if we are anything better than idiots born will we take anything less than the Government's own standard. Mayhap the authorities will say that they cannot trust us not to push in unnecessary visits if we are to be paid for work done. Be it so; but neither can we trust the patient not to take advantage of us if a capitation fee be fixed, and as the insulted party we are entitled to the first shot.

If we stand firm for this very modest payment, and if therefrom the Bill become a dead letter, the people who will think much harm will come of that must be very few and far between. Medical men as a class are educated men, and necessarily not likely to be blind worshippers of socialism and bureaucratic forms of government; nor possibly have their experiences of the moral influence of insurance in the past been such as to cause them to regret, from the point of view of the national character, any prevention of its further extension.

If medical men tamely submit to be at the beck and call of the populace, day or night, wet or fine, snow, hail or sunshine, without being paid adequately for work done, they will deserve the life of slavery to which they will undoubtedly condemn themselves. Also let them remember that they hold the position they now do, not only for their own interests but also in trust for the posterity of the profession, possibly for their own sons. One of the "six cardinal points" is that the remuneration shall be according to the will of the profession, and such as is suitable to different areas. Let the fee suitable in each area be at the rate of half-a-crown a visit and a shilling a mile for mileage, and let no single division make agreement for a penny less, and it must inevitably come to pass that in spite of their promise of the "gift" of medical attendance by the process of the outrageous sweating of the medical profession, the promoters of the Bill will find that they have perforce to give way to the interests of the medical fraternity.

I am, Sir, yours faithfully,

R. N. WEEKES, M.R.C.S. Eng., L.R.C.P. Lond.

Modbury, South Devon, Dec. 14th, 1911.

To the Editor of THE LANCET.

SIR,—The above Bill, as last passed by the Commons, provides that doctors acting under this Bill shall *not* dispense, nor supply drugs to "insured persons." This is a very serious thing, and should be amended. Doctors should now know—and if they do not it is their own shameful fault—that Clause 15, line 30, p. 17, provides that the insured person shall "receive adequate medical attendance and treatment." The same clause (5), p. 19, provides that they shall receive "proper and sufficient drugs and medicines and prescribed appliances" if ordered by the insurance doctor. The same clause (ii.), p. 20, provides that no arrangement shall be made by a "Local Insurance Committee with a medical practitioner under which he is bound or agrees to supply drugs or medicine to any insured persons." On p. 21, line 10, the right of the "assistant to any apothecary" (a licence still granted by the Apothecaries' Society, London), "to compound and dispense medicines" is preserved. But as there are not many doctors holding the Apothecaries' Society medical diploma (L.S.A. Lond.), this proviso affects very few doctors. Also, I understand, that Society does not now grant many licences as "assistant apothecaries," most men now taking the chemists' certificate from the Pharmaceutical Society. But even if all doctors could supply drugs to insured persons, it would not pay them as the actuarial reports upon the Insurance Bill are worked out upon a basis of 4*s.* per member per annum to the doctor, and 2*s.* to the chemist per annum per member. No respectable doctor could honestly supply good reliable drugs to insured persons for 2*s.* per annum. This is now especially so, as under the Bill all ages over 16 are eligible to become members, including thus Friendly Societies, Post Office depositors, old-age pensioners, those under the unemployment clauses, and those discharged from the army, navy, and mercantile marine.

Some may fancy—but they have no right to fancy, as this Bill is too serious a proposal—that because Clause 15 (3), p. 19, provides that if insured persons have an income "*exceeding* a limit to be fixed by a committee," and that such insured persons "may make their own arrangements for receiving medical attendance and treatment, including medicines and appliances," that this is applicable to *all* insured. Nothing of the kind. Clause 1 provides that there are two kinds of insured persons, "employed contributors" and "voluntary contributors." No income limit is fixed for the former, while £160 is fixed for the voluntary. But even here the Bill makes no provision as to how we are to find out an insured person's income. The fact is, no such proviso exists, or can exist. Had there been a house rent basis instead of income basis, things would have been easier unravelled.

The fact that by Clause 15, A (1), p. 20, the scale of prices fixed by the committee is binding upon the chemists emphasises my point. It will therefore be seen by those who are not "addled fools" that this Bill proposes to repeal those sections of the Medical Acts which now empower doctors to charge for the supply of drugs. It also proposes to repeal the charters of the Royal Colleges of Surgeons and Physicians, and the two Apothecaries' Societies, and also the Pharmacy Acts. Any sensible person should see that doctors must be empowered to supply, and charge for the supply of drugs in all cases where an anæsthetic is needed, in cases of poisoning, in all emergency cases, and where they are far from a chemist. I therefore suggest that the Bill be amended so as to empower a doctor to either agree or disagree to supply medicines to insured persons; that all be permitted to supply and charge for medicines supplied in all cases of urgency; and that a yearly grant of 5*s.* be granted to each doctor per member per annum, or that the scale of charges for chemists be the scale of charges for doctors who agree to supply medicines to insured persons. Further, I would suggest that it be made by this Bill for any medical practitioner to supply and charge for medicines, except in case of urgency, on and after December, 1954. There is a precedence for this in Section 27 of the Medical Act, 1858, which provides that if *any person* was practising medicine in England before 1815, whether he had or had not a medical qualification, such person was entitled to have his name entered on the Medical Register of the United Kingdom.

May I very seriously urge all Members and Licentiates of the Colleges of Surgeons and Physicians and of the Apothecaries' Societies to bring at once the above facts to the notice of their Colleges and also to the General Medical Council.

I am, Sir, yours faithfully,

Liverpool, Dec. 15th, 1911. ROBERT R. RENTOUL.

To the Editor of THE LANCET.

SIR,—Now that it has been decided not to work the Act unless the six cardinal demands are granted, we are confronted with the necessity for a definite interpretation of the words "adequate remuneration." Everyone but the Chancellor has shied at any attempt to fix a figure, even a

minimum. And the Council seemed glad to pass the responsibility on to the divisions, without a hint of the advantage of an early settlement of the minimum rate.

Most general practitioners are sore that the Council did not from the first emphatically repudiate the 4*s*. 6*d*. limit. At any rate we are now face to face with the question, and it seems to me the first essential is to fix a fighting minimum, below which all discussion with Insurance Committees, whether in town or country, is to be barred. If 4*s*. 6*d*. per head per annum is intolerable and absurd, what is tolerable and reasonable?

Naturally the remuneration should depend on the nature and scope of the treatment expected, and it is of the first importance that this should be clearly defined by the Commissioners in the immediate future. But if the Act implies no more than the medical and minor surgical attendance now given to Friendly Society members, and it will not be less, the ability to decide will not increase by waiting. Only the Council can authoritatively settle the minimum, whether the payment be per head or per item. And the latter, owing to its infinite uncertainties and nauseous clerical work, seems scarcely "practical politics" at present. The Council must, before deciding, know the feelings of the divisions and the rank and file.

Will it not be difficult for the individual practitioner to fix a provisional and personal minimum without an idea of the opinions of his branch in detail, and of the neighbouring and other branches more generally? As referenda seem likely to be the vogue, why not have one on this very point and the collected results distributed to everyone in general practice? With this information opinions could be condensed in divisional meetings for transmission to a meeting of the Representative Body, and the final result to be accepted by all announced by the Council. Afterwards at leisure the local adequacy or not of this minimum could be discussed in the branches, and a working local rate settled with the approval and assistance of headquarters.

May I suggest the Post Office rate as a minimum, the exclusion of medicine being more than compensated by the inclusion of indifferent and bad lives?

I am, Sir, yours faithfully,

Dec. 17th, 1911. A HULL PRACTITIONER.

To the Editor of THE LANCET.

SIR,—I shall be glad if some reader of THE LANCET will explain to me how it is the prices asked for practices advertised in your journal are steadily rising. I quite expected the Insurance Bill would have caused a glut in the market and a rapid fall in value, especially in "cash" practices. But two years' purchase, estimated on the *gross* receipts, seems to be the usual thing for a partnership with introduction, and anything from one year's purchase upwards for a death vacancy. Surely the effects of the proposed Bill cannot be so very terrible after all.

I am, Sir, yours faithfully,

Dec. 16th, 1911. M.D., F.R.C.S.E.

LEISHMANIA AND MOSQUITOES.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Nov. 11th there appeared a commentary by Dr. C. M. Wenyon upon my note published in the previous number of THE LANCET. Above all I thank Dr. Wenyon for the interest shown in my researches, and I am very glad that he has found in his important studies on the oriental sore the presence of different forms of leishmania in the gut of stegomyia fasciata. This confirms what I have shown in respect of the leishmania donovani and the anopheles. Moreover, I have pointed out that not only this but also some varieties of culex can be infected by the cultures of leishmania donovani.[1]

Dr. Wenyon has found, moreover, that the leishmania tropica develops in the intestine of the bed bug. I did not reach this result in my researches on the bed bugs, fleas, and lice which had sucked cultures of the leishmania donovani.[2] Basile was equally unsuccessful in infecting with leishmania humana from cultures either the human and dog fleas or the bed bug.[3] Professor Gabbi in a recent publication[4] concludes that the leishmania donovani does not live at all in the dog and human fleas, either by cultures or by splenic juice. But I cannot agree with Dr. Wenyon when he suggests that the development of the leishmania in mosquitoes cannot be natural, but must be referred probably to the sucked fluid of cultures. In my publication, I think, will be found also the answer to this observation. In this connexion I will now add: 1. If the modifications that the parasite undergoes are to be referred to the nutrient fluid they must be found much more in the pure cultural fluid and not in the gut of the insect, mixed with all the bacterial flora of the gut of the mosquitoes. This does not happen. I have said already that at some time after their introduction a great number of the leishmania lose the flagellates and tend to modify themselves; in the tubes of cultures, on the contrary, the oval oblong forms without flagellates exist only in the very old ones and with little fluid of condensation. 2. In bed-bugs, which also sucked cultures until they swelled, I never found even a trace of the leishmania, although there was in the gut an abundant culture fluid. It must be observed that the experiments on all these insects have been performed with cultures from the same strain. 3. Since it is impossible for the leishmania to develop in a non-sterile substratum it is necessary that the gut of the anopheles out of the cultural fluid be suitable to the development and existence of the leishmania. In the contrary case it would be destroyed in a short time by the gastric juice, by the great number of bacteria and the other forms of parasites so frequent in the intestinal contents of the anopheles.

I have not yet perfect knowledge of the interesting researches made by Dr. Wenyon on the stegomyia fasciata; but if the author has found (by comparing preparations) that the forms which have been found in the insect are in any respect different from those of the sore on which the insect had sucked, how would he interpret these modifications?—I am, Sir, yours faithfully,

Bologna, Nov. 27th, 1911. Professor G. FRANCHINI.

SANATORIUM TREATMENT FOR CHILDREN.

To the Editor of THE LANCET.

SIR,—All of us who are working for the better treatment of surgical tuberculosis in children must welcome the letter from Mr. W. Edmunds in THE LANCET of Dec. 16th.

A circular issued by the Board of Education in March, 1900, states, *inter alia:* "A school authority may also make provision for defective children by means of boarding them out near to special schools or classes or by means of sending them to boarding schools; and for this purpose may either establish boarding schools of its own or utilise on such terms as may be agreed institutions certified for the purpose by the Education Department."

As an example of the good work which can be done on these lines I may cite the residential school maintained by the Manchester Education Committee. This school, founded in 1905, now contains 120 beds, and is able to admit cases of surgical tuberculosis and to treat and educate them for the whole length of time necessary for cure. The work and results of the school may be found in a pamphlet published in 1910. It is only too evident to those who have made any study of the subject that our present means of dealing with cases of surgical tuberculosis in childhood are hopelessly inadequate. Treatment for an indefinite length of time in special institutions is the only possible solution of the problem. By whom is this treatment to be provided?

In spite of the truly admirable work done by a few public-spirited education authorities, I do not think that the real solution of this national question can be expected to lie with the education authority. My reasons for this view are: 1. Very large numbers of cases of surgical tuberculosis occur in the earliest years of childhood. It is especially important to secure treatment for these early cases. They cannot be allowed to wait until they are of age to come within the control of the educational authority. There can be no better comment on the need for treatment of these younger

cases then the statement of the Registrar-General that of the deaths from this cause nearly half of the victims are under the age of five years. 2. The main object of the education authority must inevitably be to educate the child, and in this way treatment will be made subservient to teaching. Under the present system of grants, quite inadequate as they are to the needs of the work, the local authority cannot afford to maintain any ailing child who is not on the register as an active scholar. 3. Action by local authorities is likely to lead to the building of numerous small scattered institutions probably of unequal efficiency and often of necessity built in climates unsuitable for the treatment of a tuberculous disease. The only efficient means of treatment is by a relatively small number of large institutions situated in the most favoured parts of the country and under the supervision of surgeons who have special experience of this branch of work.

The only authority which can be expected to carry out this work in a sufficiently broad spirit is the State itself. The State proposes to erect sanatoria for the treatment of phthisis. This is well, but the matter cannot rest here. There must be provision made for the treatment of surgical tuberculosis in children before the scheme can be regarded as satisfactory. It is our duty as a profession to show plainly that the provision of sanatoria for consumption is far from offering a complete solution of the problems in the treatment of tuberculosis, and that these children with their special form of the disease cannot be treated in such sanatoria. For this latter reason I think that the use of the word sanatoria is unfortunate when applied to any provision for the better treatment of tuberculous disease of the bones and joints in childhood, and it would conduce to clearness if the word were entirely eliminated from the literature of this special branch of tuberculosis.

I am, Sir, yours faithfully,

Manchester, Dec. 16th, 1911. E. D. TELFORD.

MISS FLORENCE NIGHTINGALE'S LETTERS.

To the Editor of THE LANCET.

SIR,—As executors of the will of the late Miss Florence Nightingale, we shall be glad to receive any letters written by Miss Nightingale, and any other materials relating to her which the owners may be willing to lend us for the purposes of a memoir.

We should respect the wishes of every friend and correspondent of hers who will kindly afford us information, and no letters will be published without the consent of the owners. Papers should be sent by registered post to the executors of the late Miss Florence Nightingale, 31, South End-road, Hampstead, London, N.W., who will be happy to give any further information.

We are, Sir, yours faithfully,

HENRY BONHAM CARTER.
S. SHORE NIGHTINGALE.
L. H. SHORE NIGHTINGALE.
A. H. CLOUGH.

KING EDWARD'S HOSPITAL FUND FOR LONDON AND ST. GEORGE'S HOSPITAL.

To the Editor of THE LANCET.

SIR,—In the report of the meeting of the King Edward's Hospital Fund for London, the following paragraph appeared:—

> Among the institutions which do not appear in this year's list is St. George's Hospital, the Governors having withdrawn their application as the result of the decision of the Fund on the question of the amounts which could properly be paid to the Medical School in respect of the work done for the hospital. The grant of £2000 which was reserved last year lapses, the conditions attached to it by the Council of the Fund not having been fulfilled.

The governors of St. George's Hospital have always endeavoured to work in harmony with the King's Fund, and much regret the difference of opinion upon a matter of principle, which they consider to be of such importance as to justify their refusal to comply with the demands of the Fund. The Governors maintain that no money whatever is paid by the hospital to the Medical School for the purposes of education.

The sum referred to has been expended upon pathological and bacteriological work, done entirely for the patients of the hospital; in other words, the money is spent in giving the patients of St. George's Hospital the benefit of the latest scientific improvements in diagnosis and treatment.

In previous years, when the same money was paid out of a discretionary fund, no objection was made by the King's Fund, but in such a case the accounts of the hospital are fallacious to the extent that the sum paid out of a discretionary fund cannot appear in the final calculation of the cost per bed.

The governors of St. George's Hospital believe that all moneys paid for the benefit of patients should be paid out of the general funds and published in the accounts. Feeling sure that no good can result either to the King's Fund or St. George's Hospital by the public discussion of the questions involved, the whole circumstances of the case are not now entered into, but a statement can be obtained by those who are interested upon application to the secretary.

I am, Sir, yours faithfully,

A. WILLIAM WEST, Chairman and Treasurer.

St. George's Hospital, S.W., Dec. 13th, 1911.

THE VALUE OF THE ALBUMIN REACTION IN TUBERCULOUS SPUTUM.

To the Editor of THE LANCET.

SIR,—With reference to the letter of Mr. H. S. Gettings in THE LANCET of Dec. 9th on the Value of the Albumin Reaction in Sputum, I have made the albumin test on 25 sputa in Dr. Morland's laboratory in Arosa with the following result: positive cases, 21; negative cases, 4. With regard to the 4 negative cases, 1 of these was a case of influenzal pneumonia, the other 3 of pulmonary tuberculosis, long inactive, 2 of which still contained tubercle bacilli in the sputum. Of the 21 positive cases, tubercle bacilli were found in 19, and on a previous occasion in one of the others. The remaining case was also undoubtedly one of pulmonary tuberculosis. These were 25 consecutive specimens of sputum sent in for routine examination. So far, then, a positive reaction has coincided with the presence of active or recently active pulmonary tuberculosis.

One point in the technique deserves notice; where only a trace of albumin is present it is necessary to add a considerable amount of saline to ensure its precipitation on boiling.

I am, Sir, yours faithfully,

M. B. CHRISTOPHERSON.

Arosa, Switzerland, Dec. 14th, 1911.

ONE BELL.

To the Editor of THE LANCET.

SIR,—I note in your otherwise appreciative review of my book, "The Surgeon's Log," in THE LANCET of Dec. 16th, that you cast some polite doubt on the statement that "one bell" is sounded at 11.45 P.M. and 5.45 P.M. The explanation is as follows: "One bell" is sounded a quarter of an hour before every change of "watch." It, therefore, is sounded at a quarter to 12, 4, 8, and in addition at a quarter to 6, this last indicating the approaching advent of the second "dog watch." The object of sounding "one bell" at such times is to remind the quartermaster who is not at the wheel to call the men who have presently to come on duty in the next watch. This warning bell has nothing, therefore, to do with the usual bell signals indicating half hours at sea. There are several other variants from the half-hour rule—as, for instance, the sounding of "seven bells" at 7.20 A.M. and 11.20 A.M.; but as your review does not touch upon these I need not occupy your space in explaining.

I am, Sir, yours faithfully,

Queen's-road, W., Dec. 15th, 1911. J. JOHNSTON ABRAHAM.

DONATIONS AND BEQUESTS.—The Royal Dental Hospital, Leicester-square, has received a donation of £200 from the Worshipful Company of Goldsmiths and 10 guineas from the Worshipful Company of Broderers.—Under the will of the late Mr. William Wright Tasker, of Hull, the testator left £500 each to the Hull Royal Infirmary and the Hull Victoria Hospital for Sick Children.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Policy of the Medical Profession in Scotland.

THE Insurance Act still monopolises the attention of the Scottish medical profession. The Scottish Committee of the British Medical Association met in Glasgow last week and resolved to recommend an effort to work the Act in accordance with the policy of the Association, the Scottish Commissioners to be told that service would not be taken unless the "six cardinal points" were conceded. The important correspondence that continues to find its way into the lay press shows the general feeling of the profession. In a letter to the *Scotsman* of Dec. 13th the Master of Elibank, Mr. Alexander Murray, replies to that paper's leading article on the subject of the Bill. The burden of his complaint is that, with regard to the *Scotsman's* assertion that the provision in the Bill for the free choice of doctor "is rendered of doubtful value" by the proviso in Clause 16, the British Medical Association agreed that the profession could not reasonably complain of arrangements that were inevitable "to meet particular local disputes possibly leading to deadlock." He denies that the Government's arrangement in regard to removal from Friendly Societies' control is "delusive." In regard to the swamping of the doctors on the Local Insurance Committees, he replies that the representation previously given to the doctors on those committees has been increased, and they have been given "the great collateral advantage that a purely medical committee, representative of the profession, must be heard in each area as to the proposed terms of any arrangement." As to the defining of the method and amount of remuneration in the Bill itself, he says that these points could not be settled at present, for "the necessarily experimental data are not available, and conditions of work must vary very considerably in different areas. Dr. Alexander Veitch, in reply to a letter from Mr. Handel Booth, M.P., points out that "payment is not everything. By serving under the Bill we part with our liberty and enter a domain of service ignorant of what will be expected of us, and not knowing what every common workman insists upon knowing—viz., the rate of pay and hours of service." He, in common with other correspondents, points out that a gibe at medical men who fear a loss of income under the Bill comes ill from those whose fellow Members recently voted one another £400 per annum out of the public purse. Dr. William Haig supports the acceptance by Mr. Smith Whitaker of the post of medical Insurance Commissioner on the ground that it is not a post of working under the Bill, but that since there is to be a medical Commissioner it is better to have a friend in such a position than one who might be indifferent or even inimical to the interests of the profession. In the *Scotsman* of Dec. 15th Dr. Ewen J. Maclean, chairman of representative meetings, and Dr. J. A. Macdonald, chairman of Council, of the British Medical Association, reply at length to the letters of Dr. Wm. Craig and Dr. J. Stuart Ross, referred to in my last communication. They state that "all the statements made by Mr. Whitaker which have been criticised were made strictly in accordance with the instructions he had previously received." That the figures as to the number of signatories to the undertaking not to work under the Bill until all the six points were included were not given at the meeting was done by explicit instruction of the committee. They repeat the warning to the profession not to overestimate their strength, and, in regard to Dr. Craig's strictures, publish a letter received by Mr. Smith Whitaker from him a few days after the November Representative meeting in London, in which Dr. Craig states that he spoke then under a misapprehension and in ignorance of the fact that the six points of the Association were still to be enforced with all powers of the Association when and where necessary. They ask what has occurred since Dr. Craig wrote that letter to cause him to revert to his former position. To this Dr. Craig replies on the following day: "It was the acceptance by Mr. Whitaker of the deputy chairmanship of the Insurance Commissioners that caused all my former doubts to recur." He points out that Dr. Maclean, in an oration to the Representatives, said in effect that if any such appointment were offered to him he would spurn it, and his decision would be irrevocable, and yet he (Dr. Maclean) was the first person to recommend Mr. Smith Whitaker to accept. He further accuses Mr. Smith Whitaker of having failed to fulfil a pledge given to him to supply him, in common with other branch secretaries, with a fuller statement and explanation as to the number of signatories to the undertaking which was withheld from the meeting, and asks what, in the light of this and other happenings, one must think. Dr. A. M. Easterbrook, in the same issue, says that in the Lothians at the present moment the undertaking not to accept service under any other conditions than those laid down in the six points is solidly signed, that nearly almost every non-member of the Association is coming in, and that the guarantee fund is now considerable, and he urges continued silent working. Dr. Allan Gray shows that after deducting practically 8*s.* for administration expenses and 6*s.* for druggist, only 25*s.* remains to pay the total average annual sickness cost per man. He shows how hopelessly inadequate the funds will be for any reasonable pay to the doctor in proportion to the amount of work entailed.

Old Royal Infirmary, Glasgow.

An interesting relic of the old Glasgow Royal Infirmary was unearthed last week, when the contractors erecting the new buildings of the institution encountered the foundation-stone of the old structure. There was a company of interested onlookers when the cavity was exposed. The contents included two glass jars, one containing a sample of muslin, which was the commodity principally manufactured in the city in 1794, the date of the laying of the stone. In the other jar were newspapers published in Glasgow at that date, also two copper coins and two silver coins, which were in an excellent state of preservation. The cavity of the stone was covered by a tin plate, which bore the inscription that the stone had been laid by James McDowall, Provost of the city of Glasgow. The first building had accommodation for 152 beds, and the citizens were extremely proud of what they called that "magnificent establishment."

Aberdeen Dispensary and Maternity Hospital.

The adjourned annual meeting of the Aberdeen Dispensary, Maternity Hospital, and Vaccine Institution was held on Dec. 14th. The report of the special committee at its first meeting after appointment on March 7th last was submitted, which recommended that the dispensary should in the future be disjoined from the maternity hospital, that in the working of the dispensary "proprietary and patent medicines should be discontinued, and that every person receiving medicine should be asked to subscribe 2*d.* for each time medicine is supplied to them." In this way the committee is satisfied that with the subscriptions and donations continued as formerly the income of the dispensary would be so much improved as to wipe out any annual deficiency. With reference to the carrying on of the maternity hospital the committee finds that an annual sum of about £900 is required, and towards providing the same the sum of £470 could be obtained from rents, grants, nurses' fees, &c., leaving a deficiency of from £400 to £450, which to keep the hospital going, and failing a subsidy from the University, must be provided from annual grants from bodies, such as the town council, and charitable trusts, and further by largely increased donations from the charitable public. With reference to the debt affecting the institutions, amounting to £4500 without interest, the committee has promises from different sources of sums of £950, £375, and £750, leaving still to be provided a sum of £2400. Lord Provost Maitland, in moving the adoption of the report, said that the position of the maternity hospital was most difficult. Under conditions specified in the report the dispensary could be worked without an annual deficit, but it seemed doubtful whether the former institution could be carried on any longer in its present condition. The special committee had approached the University Court with a request that the Court should in some way assist the maternity hospital funds. It was of importance that the institution should be continued from the point of view of the dispensary and the training of students. They felt that it was right that the University should have an opportunity of considering the position and of deciding whether, rather than have it closed, they should in some way

come to the rescue with a donation or subsidy towards a substantial part of the annual deficiency. If that could be done a special effort towards increased subscriptions could be made, but failing that it was impossible that the maternity hospital should be continued on its present lines. Other developments for the utilisation of its buildings and continuing its work on a somewhat altered basis might be possible; but he did not think that it was possible that it could be carried on on its present charitable basis. With regard to the debt, there were certain sources to which they were looking hopefully towards a further reduction, and perhaps extinction, of the sum, in which case the dispensary, which was the parent, and in some ways the most important part of the work, could be carried on, with the modifications suggested, and the committee of management could very seriously consider the position with regard to the maternity hospital. Some objection was taken to the proposed fee of 2*d.* for medicines, but ultimately the motion was unanimously agreed to. The Lord Provost said it would be well to emphasise that the motion was not inimical towards the maternity hospital.

Diphtheria in Laurencekirk.

At a meeting of the Laurencekirk district committee of the Kincardineshire county council, held in Laurencekirk on Dec. 11th, Dr. W. A. Macnaughton, medical officer of health of the county, reported that since the last meeting there had been 16 notifications of diphtheria, with four deaths, 11 occurring in the parish of Marykirk, three in Fettercairn, and two in Fordoun. It has been agreed to repaint the Marykirk school and to make a new well a little further removed from the centre of infection.

Chalmers Hospital, Banff, and Parish Councils.

On Dec. 17th there was held at Buckie a conference of the nine Banffshire parish councils to take action towards enforcing the Order of the Local Government Board granting them representation on the board of management of the Chalmers Hospital, Banff. It was decided, failing affirmative action by the trustees, to take legal action to enforce the Order.

New Hospital for Buckie.

A new hospital was opened at Buckie on Dec. 14th. The parish of Rathven is one of the most thickly populated in the North of Scotland, consisting largely of a series of fishing villages, and contains nearly a fourth of the total population of the county of Banff. Formerly cases not nursed at home were sent to Aberdeen Infirmary. It has been pointed out that, outside Glasgow, Rathven has been the first parish council to erect a hospital for the treatment of the sick poor. Provision has been made in the hospital for phthisical cases.

Epidemics in Aberdeen.

The virulence of the measles and scarlet fever epidemics remains unabated in Aberdeen. The returns for the week show 58 cases of scarlet fever, 295 of measles, and 106 of whooping-cough. Dr. Matthew Hay, medical officer of health, has published an appeal to the parents of young families and others, in which he enforces the danger of measles to infants and young children, the need of protecting such from infection, and of having medical advice and proper care when the first symptoms appear. During the present epidemic there have been 80 deaths from measles, most of them in children under two to three years. Dr. Hay notes that during the 20 years of compulsory notification of measles there were 13,451 cases among children under three years of age. Of these, about 1 in every 12 died. During the same period there were 26,923 cases above three years of age, with a death-rate of 1 in 120. Thus measles is ten times as fatal among children under three years as among children beyond that age. Dr. Hay states that one of the large pavilions in the City Hospital had been made available for measles patients. This will make possible the reception of measles on a more liberal scale than had hitherto been possible owing to the large number of other kinds of cases under treatment. The pavilion accommodates from 50 to 60 patients, and preference is being given to children under three years of age from the poorer houses. Dr. Hay concludes by an appeal on behalf of the public health committee, primarily to parents of young families, but also to every member of the community, to assist by action and advice in reducing this daily carnage of children. Had we, he says, week by week one-fourth as many deaths among adults from, say, typhus or typhoid, a sense of panic would already be stealing over the town, but being only children their deaths pass almost unnoticed outside the home. The present epidemic of measles is not of a more deadly variety than usual, but the cases are more numerous than they have been for many years, partly owing, no doubt, to the fewness of cases during the last four years.

Dec. 18th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Insurance Act.

A MEETING of the medical profession was held in the Medical Institute, Belfast, on Dec. 13th, when Mr. J. G. Cooke, of Londonderry, occupied the chair, and there was a large attendance of members of the British Medical Association and others from Belfast and the North of Ireland. Mr. R. J. Johnston, secretary of the branch and of the subcommittee appointed by the branch to look after the Insurance Bill, having given a clear and full statement as to the present position of matters, a discussion followed, in which disapproval was strongly expressed by some of the action of the Central Council in sanctioning Mr. Smith Whitaker's appointment. Others took the view that it was an error of judgment and that the Council should have first consulted the General Representative body before committing themselves to an action of which so many members of the profession were bound to disapprove. After a long discussion it was decided in a series of three resolutions (1) that measures should be taken to insure the unanimity of the profession, which (2) it was thought could be best attained by supporting the British Medical Association, by inducing those who were not members to join it, to sign the Association pledge and to subscribe to the guarantee fund; and (3) to appoint an organising committee for Ulster. Strong disapproval was expressed of the exclusion of Ireland from medical benefits, many fearing that this was expressly done with a view to beating down the fees of the medical men through the numerous new approved societies that are sure to spring up. The cost of the administration of the Insurance Act in Ireland for 1913 is estimated by the actuaries' report as £184,100 (when the machinery of the Act will be in full working order), while the total benefit for Ireland for all contributors will be £590,800; in other words, the cost of administration will be over 30 per cent. of the total benefit; while in Scotland, with nearly the same population, the total benefit in the same year would be £1,323,000, and the total cost of administration there, as well as in Wales and England, will be only 20 per cent. of the benefits.

The Typhoid Fever at Omagh Asylum.

At the monthly meeting of the committee of management of this institution, held on Dec. 13th, the results of the experts' examination into the drainage system were communicated. They showed that the asylum was in a very bad state and in a condition dangerous to health. In the laundry row, where most of the officials who worked or slept were attacked, the drains failed to stand the tests and the whole system was defective. The water-supply from the well was found to be polluted, and the heating and the ventilating systems were in many respects deficient. At present the water-supply of Omagh is being used, but it appears that, as this cannot go on for an indefinite period, the Omagh urban council has requested the asylums authorities to come to terms for the supply of water. It was decided to have all the defective drains relaid, including those around the asylum well which had been contaminated, and also to confer with the urban council as to the terms on which a water-supply could be obtained for the asylum until its own supply should be restored. It must be confessed that the cause of the epidemic of typhoid fever at Omagh Asylum remains still unsolved, and this is the third outbreak. Here we have a colony of people, with their own milk- and water-supply, and all we know is that the drains are defective and that they communicate with and contaminate the water-supply, which comes from a well. No mention is made of the milk, but it is understood that it has not been proved to be affected. In other words, we have the vehicle

for the spread of the disease (defective drains and polluted water), but how did the poison get into them, or is it really in them, or is it mere sewage pollution? What is wanted in the problem is to clear up the question of the presence of typhoid carriers in the asylum, and until this is done the inquiry into the real cause of the continued presence of typhoid fever therein must remain incomplete.

Ulster Medical Society.

A very interesting discussion on acute poliomyelitis at the first clinical meeting of the Ulster Medical Society, held on Dec. 14th in the Medical Institute, Belfast, was introduced by Dr. John McCaw, who dwelt on the symptoms, epidemiology, and treatment of the disease. Professor W. St. Clair Symmers gave an acconnt of the pathological conditions, and of Flexner's work, showing how the disease had been transmitted experimentally from one monkey to another. Dr. B. O'Brien, Local Government Board inspector, mentioned that during his inspections he had heard of cases at Larne, Bangor, Donaghadee, Holywood, Portaferry, Westport, and Lisburn. Dr. John Garman, of Bangor, related the history of three cases in one family at Bangor, and Dr. W. D. Donnan, of Holywood, and others gave their experience of cases. It is a curious fact that so many of the cases occurred at sea-side places and at a time when children were wading more than usual, during a dry season, in the tide.

Medical Inspection of School Children.

A subcommittee of the Ulster Children's Aid Society has published a report on the question of the medical inspection of schools which it has been considering during the past year. In the past summer, with the consent of the National Board and of half a dozen managers of Belfast schools, the committee examined 367 children taken from four different schools, and as a result over 50 per cent. were found to have defective teeth; 17 children had signs of external eye disease; in one school, 18 out of 50 boys had more or less defective vision; in another, 11 children out of 156; 35 per cent. had unclean heads, and 21 per cent. unclean bodies. In one school, out of 156 children only 45 were completely free from defects of nose or throat. Taking the children as a whole, about 35 per cent. had enlarged tonsils. One of the best features revealed by the inspection was that the percentage of healthy children was much higher among those of tender age. The proportion of defective children increases as age increases. Thus, in one school out of 102 children—49 girls and 53 boys—there were examined 11 children between 3 and 5 years, and 5 were completely normal in all respects; of 25 children between 5 and 7 years, 8 were normal; of 43 between 7 and 9 years, 10 were normal; of 23 over 9 years of age, only 3 were normal. So far as can be seen, the teeth begin to deteriorate from fair to bad about the ages 9 to 11, though several children were found with bad teeth at an earlier age. The committee urges the establishment of a dental clinic to be established by private subscription, and it advises the task of providing medical inspection of schools to be undertaken by the National Board for Ireland as a whole, working, so far as possible, with local committees, such as school attendance and children's care committees. It is to be feared that unless school boards are formed with the same popular control of the schools as in England little progress will be made, for at present the denomination question overpowers everything else in primary education in Ireland.

Entertainment by the President of the Ulster Medical Society.

On Tuesday, Dec. 12th, the President of the Ulster Medical Society and Mrs. McKisack gave an entertainment at the Medical Institute, Belfast, to the members of the society and their friends. About 250 were present, and an extremely pleasant evening was spent.

Inspection of Dairies in Rural Districts.

The Hillsborough rural council has unanimously adopted the following resolution:—

> That we protest in the most emphatic manner against the proposal of the Public Health Committee of the Belfast corporation to secure a right, by order from the Local Government Board, for their officials to visit and inspect cowsheds, dairies, &c., in the surrounding rural district.

In other words, if an outbreak of typhoid fever or diphtheria is traced to the milk-supply of a dairy outside the area of Belfast the health authorities of that city are to have no power to verify their suspicions and to trace the origin of the epidemic. It is to be hoped that the Local Government Board will stand firm over this opposition to public health reform.

Dec. 18th.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

Death of Dr. J. F. W. Ross.

Dr. James F. W. Ross, of Toronto, died on Nov. 18th, two days after an automobile accident. Dr. Ross, driving his own car, was hurrying to a patient outside the city when the accident occurred. He was immediately taken to the residence of Dr. R. L. Langstaff, Richmond Hill, 20 miles north of the city, but in spite of the fact that several leading physicians and surgeons of Toronto were called to attend him death ensued. Dr. Ross was one of the most distinguished surgeons of Canada. He was a past President of the Ontario Medical Association, of the American Association of Obstetricians and Gynecologists, and of the Academy of Medicine, Toronto, in the foundation of which latter institution he took a prominent part. At the time of his death he was professor of gynæcology in the medical department of the University of Toronto and chief of the gynæcological service of the Toronto General Hospital, besides holding several appointments at other hospitals in the city. Prominently identified with all the leading medical associations of the Dominion as well as of the United States, he was a frequent contributor of papers and addresses as well as an ardent participator in the discussions. Thus he enriched Canadian medical literature, and papers from his pen frequently added to the worth of many American medical publications. Of late years Dr. Ross had been largely interested in financial matters, particularly in life insurance, being one of the directors, as well as a large shareholder and medical referee of the Manufacturers' Life Insurance Company. He was born on August 16th, 1857, graduated at the Toronto School of Medicine in 1886, and after studying under Lawson Tait, and at Zürich, began the practice of gynæcology in Toronto in 1891. He was a son of the late Dr. James Ross, of Toronto, a prominent general practitioner and obstetrician in his day.

McGill University: A Successful Financial Campaign.

Realising the necessity of immediate financial aid if McGill University would continue to keep all its departments running, the governors of the institution recently waited on the Provincial Government in Quebec to ask that the annual grant from the province be increased from the petty sum of $3000 to one of $100,000. Although the Government seemed to be in sympathy with the request, it was felt by strong friends of the institution that it would be unwise, if not disastrous, to wait for the proverbially slow movement of governments in such matters, and that it would be much better to rely upon the immediate generosity of the citizens of Montreal and the friends of McGill. So a campaign was inaugurated at once, and during the week ending Nov. 25th committees were set to work to raise a fund of $1,000,000. How splendidly the committees worked and how hearty was the response to their appeals on the part of the citizens is seen in the fact that over $1,500,000 have been subscribed. All good friends of this famous institution will rejoice that the citizens of Montreal so fully realise their responsibility in the matter, and that they have contributed so handsomely. McGill University is a strong asset not only to Montreal but to the Province of Quebec, and indeed to all Canada, and it is earnestly hoped that the Government will further the cause of the institution by early granting the $100,000 subsidy annually needed to put McGill in a splendid financial position. It must be very cheering news to the two munificent benefactors of McGill, Lord Strathcona and Sir William Macdonald, neither of whom was approached in this financial campaign for subscriptions, that there are now many other friends of the institution who can be counted upon, should the need ever arise again, for tangible financial assistance to the University.

McGill University and Work in British Columbia.

The McGill University College of British Columbia was established in that province for the object of setting an

educational standard, and not for the purpose of competing with local colleges for the home students. There seems to be a good deal of misunderstanding in connexion with the prosecution of the work of this College, some asserting that it was a bold undertaking designed to be a feeding ground for the parent institution in Montreal. As a matter of fact McGill University did not force itself into British Columbia; it was invited there. The British Columbia institution is self-sustaining; consequently the charge that its cost of maintenance tended to cripple the home institution financially has no foundation in fact. The McGill interest in education on the Pacific coast of the Dominion began in 1889. At that time the Legislature of British Columbia passed an Act whereby the Vancouver High School became Vancouver College and began to give first-year classes in arts in affiliation with McGill. In 1902 affiliation was extended to second-year work. Desiring something more substantial than mere affiliation, the British Columbian people secured legislation in 1906 establishing the McGill University College of British Columbia, with the same standards as at McGill University in Montreal. It was at this time that the McGill authorities took over the arts work, and then added the first two years in applied science and later the third year in arts. The examinations are conducted by the authorities of McGill. The college is entirely undenominational, its finances are entirely separate from those of McGill University, and so it is no expense to the home institution in any way. There is a branch in Victoria. No doubt this nucleus will ultimately become the starting point for another Canadian university on the Pacific Coast.

Infantile Paralysis in Canada.

Dr. Chas. A. Hodgetts, medical adviser to the Canadian Conservation Commission, read at the last annual meeting of the Canadian Medical Association a paper upon this subject, which is published in the November issue of the *Canadian Medical Association Journal*. Prior to November, 1909, no statistics upon this disease had been collected in Canada —that is, so far as the Dominion generally speaking was concerned. At that time the Conservation Commission sent out 8000 letters to medical practitioners throughout the Dominion, to which replies were received from 316 practitioners. In this manner the histories of 658 cases were reported as occurring between Nov. 1st, 1909, and Oct. 31st, 1910. By provinces these 658 cases were divided as follows: Ontario, 354; Quebec, 187; British Columbia, 48; Alberta, 27; Manitoba, 17; New Brunswick, 12; Saskatchewan, 6; Nova Scotia, 6; Prince Edward Island, 1. In those cases (528) in which the sex was stated 293 were males and 235 females. In 554 cases where age was stated 23 were under the age of 1 year. In the first year of life there were 69; in the second, 105; the third, 66; the fourth, 62; the fifth, 39; the sixth, 34; the seventh, 12; the eighth, 24; the ninth, 10; the tenth, 12: the eleventh, 10; and the twelfth, 10. Two cases occurred at 60 years of age and one at 65. Between the ages of 1 and 5 years, 341, or 64 per cent., were noted. The month of maximum frequency was August, 76 per cent. of the cases occurring in August, September, and October. Under dry and dusty conditions 279 cases occurred. The disease assumed epidemic form in Hamilton, Ont., and North Hatley, Quebec. There were 46 deaths, or 7 per cent., in the 658 cases reported.

The Insane in Ontario.

There are now in the Province of Ontario 6803 insane persons, or about 1 in every 367 of the population. The *Bulletin of the Ontario Hospitals for the Insane* states that most of these might have remained sane and lived useful and happy lives if they had known certain facts and acted accordingly, or if they had received proper guidance in youth. This opens up a wide field for preventive work. The number of insane in the province has increase 61 per cent. since 1890, when those having institutional care numbered 4210. The increase is due to the fact that a larger proportion of the insane are now sent to the provincial hospitals. These institutions in the province are no longer asylums or houses of detention but well-equipped modern hospitals. The cost of caring for these unfortunates last year amounted to $1,043,145.57, while for the past ten years the total cost has amounted to $9,351,094.07. There are at present 648 persons in these institutions who have been patients continuonsly for the past 20 years.

Notes.

In the new Canadian House of Commons there are 19 medical men in a total membership of 221—1 in 12. One, Dr. T. S. Sproule, has been elected Speaker.—Quebec city is to have a hospital for consumptives. The provincial government has recommended a legislative grant of $3500 per annum for maintenance of the institution, which is to cost $60,000. It will be administered under the medical control of Laval University of that city.—Dr. J. E. Dube, Montreal, president of the Medical Board of Bruchesi Institute, has been awarded a gold medal by the International Society against Tuberculosis for his active work campaigning against the "white plague."—The British Columbia Medical Association at its recent annual meeting elected the following officers for the ensuing year: President, Dr. J. D. Helmcken, Victoria; Treasurer, Dr. C. J. Doherty, New Westminster; Secretary, Dr. A. S. Monro, Vancouver.—The Montreal Maternity Hospital treated during the last hospital year 802 patients. The total expenditure for the year was $28,057.

Toronto, Dec. 8th.

UNITED STATES OF AMERICA.

(FROM OUR OWN CORRESPONDENTS.)

Popular Distrust of the Medical Profession.

IN an address at the New York Academy of Medicine recently Professor James Ewing dealt with the increasing distrust of the medical profession shown by the general public. He said that grave defects in the standard of medical education had been disclosed. They were freely admitted, but the public had been mystified and a serious suspicion had been aroused in regard to the general competency of medical practitioners. Prevailing public sentiment was out of touch with the medical profession. This was seen in the crude and halting manner in which medical topics were handled by distinguished writers, clergymen, lawyers, statesmen, and public officials. It was also evidenced by the wide extension of Christian Science and the wavering defence which legislatures afforded to the public health against the depredations of irregular and incompetent practitioners. Dr. Ewing thought that the present public distrust rested to a large extent on an inherent defect in the public mind itself. Whether from mental deficiency, superstition, the narrowing influence of the Church, or the educational system of the last centuries, with its incongruous schooling in rigid mathematics and speculative philosophy, the modern mind was unfitted to grasp the delicate and infinite variety of biological processes. He suggested that in the circumstances it might be good policy for the more enlightened public of to-day to analyse the grounds for its disaffection and to make sure that it was not merely repeating the suspicions of the Middle Ages. Dr. Ewing pointed out that most American communities were particularly delinquent in the adoption of measures demonstrated by medical science to be necessary for the protection of the public health. There was, according to the speaker, a general failure in America to appreciate the importance of a high development of sanitary science to a well-ordered community. He also referred to the difficulties under which the prosecution of medical research laboured. He cited the opinion of a university president that the ranks of medical science had to be largely recruited from those who could get along without earning a decent income. This was the tacit policy of all American medical schools. The results were that the material resources for medical science in America were greatly inferior to those available in Germany and France.

New Regulations for Medical Practice in Canal Zone.

President Taft has given an order recently requiring all persons, other than United States Government medical officers, who desire to practise medicine on the Isthmus of Panama to obtain a licence from the Board of Health of the Canal Zone.

Proposed New Medical Buildings for Columbia University.

In the annual report of the President of Columbia University just issued Dr. Butler asks for $6,000,000 (£1,200,000) to build and equip a new medical building for the College of Physicians and Surgeons of New York,

the medical department of Columbia University. By an agreement between the Presbyterian Hospital, New York, and the College of Physicians and Surgeons, the latter has obtained the right to use that hospital for teaching and research. In return Columbia University is to pay the cost of the scientific and educational side of the work, of all equipment for the laboratories, and of maintaining those parts of the hospital plant that are used chiefly for scientific and educational work.

Further Factory Legislation Needed.

Mr. Louis B. Schram, President of the New York Civic Federation, has been pointing out the need for better laws in New York State to regulate the safety of factories. Giving evidence before the Factory Investigation Commission, Dr. Woods Hutchinson said that his visits to several factories during the strike of the shirt-waist makers had convinced him that the factories were conducive to ill-health. Bad air, poor light, over-crowded work-rooms, and inadequate exits were found in every factory visited. Alcoholism as a factor in causing accidents to workmen was also referred to. It was decided by the commission that the director of the Museum of Safety should prepare statistics and engage lecturers on this subject.

Bad Condition of Bakeries in New York.

Dr. E. J. Lederle, commissioner of health for New York City, in giving evidence before the Factory Investigation Commission recently, said that he had investigated many bakeries in New York City, and had found conditions very bad. Drastic remedies were called for to better conditions.

Campaign against Infantile Paralysis.

The New York Board of Health has taken steps to endeavour to abate the prevalence of acute poliomyelitis by assigning medical inspectors to all orthopædic hospitals to insure complete reports of cases therein treated. Isolation of all cases has been suggested, and the keeping other children of affected families from school. Circulars will be issued to every family in which a case occurs, giving information as to the disease and its treatment, and a minimum quarantine period will be established. Bedding will be disinfected, and houses in which a case occurs will be either renovated or fumigated. A circular calling attention to these requirements will be sent to all medical men in New York, and in future they will be required to report promptly to the health board all cases they are called on to treat.

Schools in Chicago to Teach "Little Mothers."

In future one room in each public school building in Chicago is to be set apart for the instruction of girls in the care of infants. The Chicago Board of Health will supervise the work and will furnish the equipment.

Dec. 11th.

NOTES FROM SOUTH AFRICA.

(FROM OUR OWN CORRESPONDENT.)

A Curious Government Commission.

THE patent laws of the Union evidently require revision—at any rate, they should be administered in a sensible manner by the Minister of Justice. In Cape Colony patents can be granted for a period of 14 years, and can be renewed if it is proved to the satisfaction of the Governor General in Council that the patentee has not received sufficient remuneration for his invention. There are a number of conditions to be complied with before a patent can be granted. Besides purely formal conditions it is necessary that an article, in connexion with which application for patent rights is made, should be described in the specification in a sufficiently clear and distinct manner to enable it to be reproduced from the description alone by anyone trained in the particular business, trade, or calling; also that it should be original and have necessitated some ingenuity, skill, and industry for its production; and that if granted so long as the patent right lasts it should not vary in any essential detail from the specification. Patents for quack medicines and alleged remedies have been granted indiscriminately throughout South Africa in the past. It would seem that the patenting of a quack remedy materially assists in its sale, possibly because it is regarded by the public as an article which has received the approval of the Government. At any rate, a patentee whose patent was about to expire, has endeavoured to induce the Government to sanction its renewal. The Government not refusing to consider the application, the patentee briefed a barrister to appear on his behalf in connexion with a commission. The members of the Commission consisted of two judges of the Supreme Court, a King's Councillor, a medical man, and an analytical chemist, and these gentlemen, with the exception of one of the judges, who was unable to attend, had to occupy a day in hearing the application, at no small expense to the taxpayer. The articles covered by the patent consist, according to the specification, of one for "outward cancer" and one for "inward cancer," the former being applied externally and the latter being administered by the mouth. The ingredients of the remedies are specified in each case under two headings, "principal" and "secondary," the latter being added "according to circumstances." The "principal" ingredients to the alleged remedy for "outward cancer" are specified as consisting of alum, borax, lime, lard, and vaseline; the "secondary" ones as zinc sulphate, potassium permanganate, raw linseed oil, sugar candy, sulphur, and "plumbi-lion" ointment. In the "inward cancer" cure there are given as the "principal" ingredients white arsenic, borax, and conium, and as the "secondary" ingredients zinc sulphate, potassium permanganate, sugar candy, hypericum perforatum, and "anti-cancerosa." The Cape Province Medical Council, represented by its legal adviser, opposed the application on the grounds that no particular ability or industry was disclosed, that no benefit had been conferred on the public, and that the invention was of no practical utility, but, on the contrary, might be hurtful. The applicant gave evidence in support of the application and was somewhat severely handled by the opposing barrister and by members of the Commission. He admitted that he was in the habit of rubbing in the ointment in cases of "internal" cancer and of giving the mixture when it was "external"; also that no specific quantities of the different drugs were adhered to in manufacturing the preparations. He was unable to say what "plumbi-lion ointment" or "anti-cancerosa" consisted of, or what preparation of conium or hypericum perforatum he used. He, however, pleaded that he had cured animals and human beings, that it was of much benefit to the country, that most of his patients were treated gratuitously, and that he had never made more than £100 per annum out of the patent. Mr. Justice Hopley remarked that he did not seem to have been selling a patent at all, but appeared to have been prescribing for individual cases, and that he was at a loss to understand how the original patent was ever granted. The applicant's evidence was remarkable in several respects. Thus, he at first denied he had ever been convicted for contravening the Medical and Pharmacy Acts, but subsequently admitted having been fined, though, so he stated, he did not know what for, as the proceedings of the court had been held in English, and he was not conversant with that language. The decision of the Governor-General in Council will depend upon the report made by the Commission.

That such a commission should have been appointed at any rate inaugurates a new policy, and shows that the Government does not intend granting patents for quack remedies as readily as has been the case in the past, without at least an inquiry. It is doubtful whether in any country patent and proprietary medicines are granted such facilities as in South Africa. The trade in such articles is practically unhampered by legislation and is carried on under no supervision whatsoever. The public would, I think, be surprised if an analysis of some of these remedies was made, and the results published. Many of the remedies are so-called "Dutch medicines," of which the principal ingredient in some cases is some form of alcohol; and these are freely used in many of the back-country districts, particularly for infantile ailments. It is very necessary that legislation should be introduced to prohibit the sale of at least such remedies as are pronounced by competent authorities to be harmful or injurious to health, but there does not seem much prospect of this in the present state of public indifference.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Sanitary Congress at Bombay.

AN official Sanitary Congress at Bombay was opened on Nov. 14th last by the Hon. Mr. S. H. Butler, at which 28 delegates attended. Mr. Butler welcomed the delegates on behalf of the Indian Government, and thanked the local administrators for the presence of the delegates. The conference, he said, gave an opportunity for zealous workers in different parts of India for comparing experience, exchanging ideas, and above all, setting up that energising friction of mind with mind, the want of which most men toiling in isolation feel at times as a burden well-nigh intolerable. He hoped this would be the first of a series of such conferences. After referring to the various topics on the agenda of the conference, the Honourable Member for Education and Sanitation said the basis of all sanitary achievement in India must be a knowledge of the people and the conditions under which they live, their prejudices, their habits, surroundings, and financial means. This was emphasised in the memoradum placed on the table of the Legislative Council at its last meeting by Surgeon-General C. P. Lukis, to whose ability Mr. Butler paid a tribute. Ardent spirits, he said, who may think that sanitary measures possible and effective in the West must be possible and effective in India, will flap their wings in vain, and set back the cause which claims their laudable enthusiasm. (It is only fair for your correspondent to add here to this remark that such a statement does not apply to the various sanitary commissioners and health officers in India, whose special qualifications and experience of Indian conditions are sufficient guides to them in their various recommendations. Mr. Butler believed in the slow and sure results of education being the forerunner of sanitation. To-day the forefront of a sanitary programme must be (1) a reasoned account of the conditions and circumstances which affect mortality and the increase and decrease of populations; and (2) a study of the relative effects of various diseases, of personal environment, and of the social and economic conditions in the different parts of the Indian Empire. "We have (he said) to work out our own sanitary salvation. We have to study the epidemiology and endemiology of our communicable diseases, the so-called 'tropical diseases'—plague, malaria, cholera, and dysentery—in order that, having ascertained the actual sources and modes of conveyance, we may determine scientifically the particular methods requisite for their avoidance, prevention, and suppression, and that we may apply with precision those methods which it is possible and politic to adopt, and we cannot do this without the assistance and coöperation of Indians themselves. In this harnessing of the science of the West to the varying conditions and circumstances of India, we must keep our standards high." For many years the Government has built up a body of investigators and specialists who are second to none in Europe, and of these he instanced Sir Ronald Ross and Sir David Semple. He referred to tuberculosis, which Dr. J. A. Turner, health officer of Bombay, had shown to cause a mortality considerably higher in Calcutta and Bombay than in cities like Glasgow and Birmingham. The question of the milk-supply was therefore of urgent importance, and he was glad to see a special paper was to be read on this subject. Two officers of the Indian Medical Service, Major E. D. W. Greig and Captain F. P. Mackie, had been deputed to study sleeping sickness, and a monograph by the latter officer was now under publication. To prevent the introduction of yellow fever into India Major S. P. James, I.M.S., had to visit various endemic areas to study methods of prevention. Great results are expected from the recently constituted Indian Research Fund, the first meeting of the governing body of the fund being held on Nov. 15th. The nucleus of the fund is 5 lakhs of rupees, granted by the Government of India, to which contributions are expected from the public. The Government of India last year assisted provincial revenues by a crore of rupees, of which 50 lakhs went to the aid of the Bombay Improvement Trust. He specially brought to the notice of the delegates the good results obtained in Frasertown (Bangalore), which still continues plague proof, and he asked, Is it an impracticable dream to construct a model town or quarter of the town in each province, with good water-supply, efficient drainage, rat-proof and mosquito-proof houses, and an adequate sanitary staff as a measure of demonstration and education? Though the difficulties were many, and ignorance and hostility of the masses were still fundamental obstacles, yet, he said, a thousand difficulties need not make a single doubt. The more enlightened minds of India have awakened to the importance of sanitation, and he had no doubt the delegates would go forward with intrepid confidence in the ability of science to create an environment in which man's higher aspirations can be fulfilled.

A resolution was passed expressing regret at the death of Colonel J. T. W. Leslie, I.M.S., late Sanitary Commissioner with the Government of India. Schemes of urban sanitation were then discussed. The subject of opening up congested areas followed. The action taken in Madras of experimenting with construction of model houses was explained by Mr. Hutton. Mr. Orr and Mr. Turner dealt with the plans under consideration in Bombay. Major W. W. Clemesha, I.M.S., read a paper on Septic Tanks, and advocated their introduction. Mr. Hutton read a paper on Water-supply and Drainage in Madras. Captain W. A. Justice, I.M.S., read a paper on Rural Sanitation and Major E. Wilkinson, I.M.S., a paper on Milk-supply and Vital Statistics. The subject of a Food and Drugs Act was also discussed.

Lahore.

Sanitation in Lahore is making great progress. A special subcommittee was recently appointed by the municipality to consider the sanitation of the city. Of 14 recommendations by the health officer 10 were agreed to. The Government of India is likely to give a grant to the sewerage scheme, and in connexion with this Surgeon-General C. P. Lukis, I.M.S., and Major E. Wilkinson, I.M.S., went round the city and various parts of the civil station with the health officer (Dr. A. G. Newell), with whom was the new municipal engineer (Mr. Longdin). The scheme is on the Shone system and will cost 15 lakhs, but is likely to be somewhat modified. A tuberculin dispensary has been advocated by the health officer. Small-pox has broken out.

Calcutta.

The Municipal Act is to be altered. A tuberculin dispensary, advocated by the health officer (Dr. T. F. Pearse), has been deferred for a year. Cholera has again appeared.

Cawnpore.

The municipality is going to purify its water-supply on the Peuch-Chabal system.

Delhi.

Unfortunately small-pox has broken out and is now counting 20 deaths a day. A special staff has been engaged. The sanitary arrangements in connexion with the Durbar are lavish.

Rawal Pindi.

A sewerage scheme is likely to be aided by a grant from the Government of India.

Nov. 20th.

Obituary.

EDMOND FAURIEL TREVELYAN, M.D. LOND., F.R.C.P. LOND.

WE have already recorded, with great regret, the death of Dr. E. F. Trevelyan, of Leeds, which took place in that city on Dec. 11th.

Dr. Trevelyan, who was the son of a former vicar of St. Paul's, Warwick, was born in that city in 1859. He received his medical education at St. Bartholomew's Hospital, and in 1885 took his B.Sc. at London University, becoming a Member of the Royal College of Surgeons of England in the same year. In 1886 he took the M.B. of London with honours at both the Intermediate and Degree Examinations, and in 1887 proceeded to the degree of M.D. He spent some time after graduation in study at Vienna and Berlin. Having held the post of house physician at the Seamen's Hospital, Greenwich, in 1887 he settled in practice at Leeds, where the whole of his subsequent professional life was passed. He became a Member of the Royal College of Physicians in 1893 and a Fellow in 1901. He was appointed in 1894 professor of pathology at the Leeds Medical School, at that time a department of the Yorkshire College, then affiliated to

Victoria University, but at the present time the medical department of the University of Leeds. The energy he put into his work when occupying this chair was remarkable. Under his guidance that department developed into one of great importance, and it was a constant source of wonder how he managed to perform the duties with such zeal and energy, burdened as he was with a multitude of other activities. When he finally became unable to cope with the duties he retired in favour of a whole-time professor, but he did not therefore rest, for he became professor of therapeutics at the University of Leeds, a post which he resigned only about two years ago.

Early in his career Dr. Trevelyan joined the honorary staff of the Leeds Public Dispensary, and at the time of his death he was its senior honorary physician. In 1894 he was elected assistant physician to the Leeds General Infirmary, and full physician in 1904, retaining the latter post also until the time of his death. Among other appointments he held those of physician to out-patients and honorary pathologist at the Leeds General Infirmary, and senior physician to the Leeds Sanatorium for Consumption.

It might be thought that an extensive consulting practice, conjoined with university teaching posts and hospital appointments, would yield a sufficient scope for the activities of any man. Dr. Trevelyan, however, was not content to limit his horizon to strictly professional affairs, and he interested himself greatly in educational, philanthropic, civic, and military matters. He was an earnest and active supporter of the Leeds Institute of Science, Art, and Literature, of which he was a vice-president as well as chairman of its committee. He had been closely identified with the educational work of the institute previously to the taking over of its schools and classes by the Leeds Education Committee.

In 1903 Dr. Trevelyan delivered the Bradshaw lecture at the Royal College of Physicians of London, taking for his subject Some Observations on Tuberculosis of the Nervous System. He was the author of the article on Acromegaly in Allbutt and Rolleston's "System," and at one time contributed considerably to medical literature, among others THE LANCET, *Brain*, and *International Clinics*.

When in 1899 Colonel Harding, then Lord Mayor of Leeds, called a meeting to organise the local fight against tuberculosis, Dr. Trevelyan became one of the most ardent supporters of the movement. The Leeds Association for the Prevention and Cure of Tuberculosis was the outcome of this meeting, and Dr. Trevelyan added to his other numerous duties that of honorary physician, and later honorary secretary, of the association. Of that movement he was the life and soul, and the city of Leeds owes to him on that account a deep debt of gratitude. He was, moreover, a city magistrate, and on the day of his death a touching tribute was paid from the bench at the city police court by his colleague, Sir George Cockburn, who presided.

On the inauguration of the Territorial movement Dr. Trevelyan was persuaded to take the command of the 2nd Northern General Hospital (Royal Army Medical Corps). It was during his service at the hospital camp at Aldershot, in August last, that the early symptoms of his illness first made their appearance. He was removed to his home at Leeds, but was never able to resume practice. About seven weeks ago he underwent an operation, and another some five weeks ago. Notwithstanding the success of the operations, however, he succumbed to an attack of heart failure on Dec. 11th at the comparatively early age of 52. His funeral took place on Dec. 13th in the Lawnswood cemetery, Leeds, and was attended by deputations from the Leeds Association for the Prevention and Cure of Tuberculosis, the General Infirmary, the Leeds Public Dispensary, the Leeds Institute of Science, Art, and Literature, the 2nd Great Northern General Hospital (R.A.M.C.), the West Riding of Yorkshire Territorial Association, and the West Riding Field Ambulance.

Dr. Trevelyan was not married, his nearest surviving relatives being his sisters, Miss Trevelyan and Mrs. Hicks (wife of the Bishop of Lincoln), and a niece and nephew.

A correspondent writes: "Dr. Edmond F. Trevelyan was a man who will be missed by many and sorely missed by a few. It may have been said of him that he had not the genius for making friends, but this does not put the matter correctly. He made friends slowly, but once made they were good ones, and the friendships lasted. The explanation of this lay in his temperament. He was by no means optimistic; indeed, he took life very seriously, and only to his intimate friends was the nod of recognition brightened by a smile which seemed at once to alter the apparent nature of the man and give a glimpse of a genial and kindly soul which the majority of his acquaintances never suspected him to possess. The keynotes of his character were industry, earnestness, persistency, and a readiness to accept additional responsibilities without counting the cost. Trevelyan had so many irons in the fire that he should have been very methodical in his arrangements. But this was not the case, and the naturally ensuing difficulties were a source sometimes of vexation, but more often of amusement, to those who were associated intimately with him in work. There was one fact in his career which he felt keenly. Notwithstanding his length of service in charge of out-patients at the infirmary he never obtained the ward appointment. This was the main reason why after ten years' service an assistant physician at the Leeds General Infirmary is now elected physican to the infirmary in charge of out-patients. This hardship, however, had an indirect effect upon Trevelyan's outlook and aspirations, gradually leading him to regard the study of tuberculosis as his chief life-work and not as subsidiary to his work at the infirmary. Trevelyan's persistency was very noticeable in controversy. There was no compromise about him. Only when he saw himself hopelessly beaten would he agree to accept what would probably not have been conceded but for his dogged opposition. His attitude in controversial matters, however, was never suffered to interrupt or cloud his relations with his colleagues; and after the fight was over he was ever ready to smoke the 'pipe of peace.' Trevelyan's manner of speaking was dogmatic and very impressive, and he had the just reputation of being a sound and lucid teacher of general medicine. He was, as I have tried to indicate, a man of marked character and of very definite peculiarities. The latter struck the observer first, while the character was capable of being appreciated only when the man was thoroughly known. That he was honourable in every thought and action and always perfectly straight his colleagues knew, and on the development of his final illness, without exception, they were greatly concerned at the sufferings of one who had earned their respect by his sterling qualities and their goodwill by his kindliness of heart."

GEORGE HUBERT MAPLETON, M.B., C.M. EDIN.

Dr. George Hubert Mapleton died at his residence, "Goldwell," Goudhurst, Kent, on Sunday, Dec. 10th, aged 53 years, from septic laryngitis after a very short illness. He went to bed on Friday and died on Sunday. Tracheotomy was performed very early on the morning of that day. This gave him considerable relief, but he passed away in his sleep in the afternoon. He will be greatly regretted by many friends and patients, and not the least amongst the poor. He was attended during his last illness by his neighbour, Dr. D'Arcy Harvey, in consultation with Dr. E. L. Adeney and Dr. T. C. Guthrie, of Tunbridge Wells.

Dr. Mapleton was born in 1858 at Saxby, Leicestershire, from which place his father, the Rev. Reginald John Mapleton, became the incumbent of St. Columba's, Kilmartin, Argyllshire, afterwards being appointed Dean of Argyll and The Isles. Dean Mapleton was a man of great literary ability and a noted archæologist, and was locally known as "The Bishop." Dr. Mapleton, after studying at "Glenalmond," proceeded to the University of Edinburgh, where he graduated M.B. and C.M. in 1880, afterwards proceeding to Vienna for special medical study. He held the position of house physician at the Royal Infirmary at Edinburgh and at Glasgow. After a short period of medical service at sea he became Government medical officer at Montserrat and afterwards at St. Kitts, West Indies. At the latter place he was police surgeon and assistant surgeon to the Cunningham Hospital. After 14 years of medical practice in the West Indies he went to Goudhurst in 1896, practising there until his death. There he held almost all the public appointments and clubs, being medical officer and public vaccinator for the Goudhurst district. He married Harriet Burley Johnson, eldest daughter of Dr. Burdett Johnson, of Montserrat. She has been left a widow with three sons and one daughter. Dr. Mapleton took a keen interest in his profession, and his abilities as surgeon and physician were

much appreciated. He gave his best advice and attention to many cases where there was little, if any, prospect of pecuniary recompense. He had two brothers in the Army Medical Service, one of whom was in charge of the Intombi camp for women and children during the siege of Ladysmith.

THE NATIONAL INSURANCE ACT.

APPOINTMENTS UNDER THE INSURANCE COMMISSION.

Sir Robert Morant, Chairman-Designate of the Insurance Commission for England, has issued under date Dec. 14th, 1911, a notice referring to the appointment of staff under the Act, premising that the notice does not refer to Unemployment Insurance. Sir Robert Morant says:—

"No announcements can yet be made as to the number or character of the posts that are to be filled in appointing the staff of the Commission. Various questions have to be decided as to the kinds of work first to be undertaken and the particular nature of the experience and qualifications most likely to be useful for carrying out these different departments of the work effectively. The Commission will need time for the careful consideration of these matters, and also for consulting with the Advisory Committee to be set up under Clause 57 of the Bill, in regard to the best ways of dealing with the main elements of the problem. As their deliberations proceed, and the Commission find any particular posts to be necessary for which applications from outside the Civil Service are needed, announcements will be made from time to time in the press. The Civil Service Commission have promised their assistance and coöperation to the fullest extent in regard to the selection of staff; and in these and other ways every possible step will be taken to secure that no appointments shall be made, whether from within or without the Civil Service, on any grounds other than fitness for the duties to be undertaken in each case.

Meanwhile the following points should be noted by all persons desirous of seeking employment under the Commissioners:—

A. No application will be considered unless it specifies the kind of post sought for and the special qualifications for that post possessed by the applicant, and application should be addressed solely to the offices of the Insurance Commission, Whitehall, S.W.—marked on the envelope 'Applications.'

B. Under no circumstances should applications, or correspondence in connexion with applications, be sent to the private address of any of the Commissioners.

C. No persons should apply for posts under the Insurance Commission unless qualified in a high degree by special knowledge and experience appropriate to the positions for which application is made.

D. The Commission cannot undertake to acknowledge or reply to any applications.

E. No interviews can be accorded to, or in respect of, applicants for posts, unless previously arranged by correspondence.

F. Any attempts made by candidates seeking posts, of whatever nature or grade, under or in connexion with the Insurance Commission, to enlist support for their applications on political grounds or for political purposes, whether through Members of Parliament or in any other ways, will be regarded as disqualifying such candidates for consideration or for employment by the Commission in any form."

THE PROTEST MEETING AT MANCHESTER.

A large and enthusiastic meeting of members of the medical profession was held in the Midland Hall, Manchester, on Thursday afternoon, Dec. 14th, under the chairmanship of Mr. G. A. Wright. The hall was crowded and the numbers were estimated at 2000. Among those present on the platform were: Sir James Barr (President-elect of the British Medical Association), Dr. T. R. Bradshaw (Liverpool), Dr. E. S. Reynolds, Mr. A. H. Burgess, Mr. W. Coates, C.B. (Manchester), Dr. R. C. Brown (Preston), Dr. J. A. W. Watts (Hyde), Mr. J. M. Ferguson (Burnley), Professor A. M. Paterson, Dr. T. B. Grimsdale (Liverpool), Professor Judson Bury, Professor W. Thorburn, Dr. A. Donald, and Dr. T. A. Helme (Manchester). Mr. P. C. Raiment represented the executive of the proposed meeting in London at the Queen's Hall. Deputations also attended from Shropshire, Mid-Wales, Hereford, Winchester, Folkestone, Dover, and Chatham.

Dr. J. S. PROWSE, the secretary of the movement, stated that letters of support from 200 to 300 medical men throughout the country had been received, and that 12 divisions of the British Medical Association and five other medical societies had approved their attitude.

The CHAIRMAN said that the former meeting at Manchester decided that unless all the essential conditions were guaranteed the profession would not be able to undertake the work proposed by the Bill. Now that the Bill had passed the House of Commons without sufficient guarantees, and the warning had been disregarded, they were there to say that they would not do the work till the Act was amended and all the essentials were provided. This was no change of front as far as they were concerned. It was the original position taken up by the British Medical Association. They would not neglect sick people or refuse to work under a good Insurance Act. The present Bill, bad as it was, if it were fully amended, would be one under which the profession would work, but it must be fully amended. They refused to work this Act as it stood. Some difficulty had arisen from the action of the Council of the British Medical Association. The real difference between them was that while the Council of the Association was prepared to put its trust in things that might happen, most of the profession preferred not to give a blank cheque to Mr. Lloyd George. Their confidence in the discretion of their representatives was shaken. It was idle to say that the demands of the profession had been acceded to or that they had any security. They would see with deep regret the disorganisation of the British Medical Association. They were not hostile to it, or even in rivalry with it, but they felt that a grave and vital emergency had arisen, and that since their first line of defence had wavered seriously they must bring up the reserves to prevent their position from being rushed. They, therefore, proposed to ask all those in the profession who were not organised to join in with existing organisations till the crisis was past. They hoped that then with increased strength both in numbers and *morale* the British Medical Association might go on with its work.

Dr. J. SACKVILLE MARTIN (Leigh) proposed the first resolution:—

That this meeting of the medical profession, in pursuance of the resolution passed unanimously on Nov. 18th and generally adopted throughout the country, now recognises that the only satisfactory method of meeting the situation created by the Government is for the members of the profession to refuse to form a panel under the Bill or to undertake any duties which the Bill proposes to assign to them.

Dr. Martin said that the policy of the Council did not reflect the opinions expressed at meetings of the members throughout the country. The Council proposed, instead of one broad fight, to split it up into many small sectional fights (cries of dissent and approval). Under this plan each division would primarily have to fight its own battle, and afterwards it might be assisted by the strength of the Association. That policy was disastrous; it practically committed them to working the Bill. They would find themselves haggling over prices in different districts, and there would be different prices. Where they lost in one division that division would be held up as an example to others. He denied that the organisation was intended to cause a split in the profession. There was a split, but it did not begin that day. When the Council recommended Mr. Smith Whitaker to accept the post of Commissioner the Association was split from top to bottom. They did not wish to widen the split, but to see if it could be repaired.

Dr. FERGUSON, in seconding the resolution, went over the six cardinal points and declared that none of them had been guaranteed. He said that if the profession would unite they had the necessary machinery in the British Medical Association, and that they could make it work as they wished.

Dr. PERCY R. COOPER proposed as a rider to the resolution the words: "Unless and until the cardinal points are fully agreed to." This was not accepted by the meeting.

Dr. HELME supported the resolution in a vigorous speech which roused the meeting to a high pitch of enthusiasm. He dissected the recent assurance of the Council of the British Medical Association that "there is no legal

barrier against the profession securing the fulfilment of its entire policy." He said that the whole thing bristled with legal and practical barriers which were unsurmountable. Medical men would be helpless once they formed a panel. If they undertook to work the Bill as it then stood in law they would have to take whatever was given them. The Commissioners could do anything they liked, even take away free choice, except increase the total amount available for payment of medical services. Dr. Helme contrasted the two alternative courses. He declared that the policy of the Association—to negotiate and procrastinate—was plunging the profession headlong into disunion. But there was still a chance for all to unite honourably by adopting the other plan, "to at once decline to form a panel or to take office under the Bill as it now stands. To tell the Commissioners at once that the only way for them to work the medical benefit is to give that benefit as a contribution to the insured. In this way we shall remain an independent profession." He claimed that this policy did not wreck the Bill, but used it. They offered to work the Bill on their own terms, for which there was provision already made in the Bill. He did not wish to wreck either the Association or the Bill, but to remove from each an obnoxious element.

At this point Dr. J. H. TAYLOR, of Salford, a member of the Association's Council, with the chairman's sanction attempted to address the meeting in defence of the Council's action and policy, but his presence was strongly objected to, and after much hostile interruption he was told by the chairman that his time was up. Dr. Taylor, amidst great disturbance, appealed to the profession to keep its head. He came before them as a member of that much-maligned and grossly abused body the Council, and he came without a word of apology. His final words were: "We are willing to work as one body, if you will only let us."

The resolution was then put to the meeting, and was carried by an immense majority, only about six members dissenting.

Mr. COATES then moved the second resolution:—

That in the opinion of this meeting it is advisable to form at once a National Medical Union to deal immediately with the conditions arising out of the National Insurance Bill, and to strengthen the hands of the members of the British Medical Association and all other societies and committees now engaged in safeguarding the interests of the medical profession.

Mr. Coates said that the union was required because the will of the medical profession had not been allowed to prevail. They left this matter in the hands of the Council of the British Medical Association, who asked for a mandate which was ungrudgingly given and asked for a fund which was generously subscribed. The "cardinal points" which the Council had been asked to secure in the Bill were as distant as Rome, as extinct as the dodo. The Council had been caught in a net: the subtlety of the spider had been too great for them. The new union must be used to purge them of the Council. It should be an emergency organisation of the whole profession of Great Britain for coördination of the members and non-members of the British Medical Association, for voicing the attitude of the profession towards the Bill as it now stood for enactment, and for facilitating an organised refusal of service under the Bill. The union would remain in existence so long as any question arising under the Act remained in dispute. It should be supplementary to, and should work with, the members of the British Medical Association.

Dr. WATTS seconded. He said that the profession must protect itself because it had been treated with cynical disregard from the beginning. By passing the Bill the Government had challenged them; their object in forming the union was to accept the challenge. Dr. Watts also disclaimed any desire to wreck any existing association. He was afraid that the Council of the British Medical Association had been obsessed by the Chancellor's personality.

Dr. D. S. DAVIES (Bristol) wished to move an amendment, but this was ruled out of order. He said he could not understand how unity could be promoted by the formation of another union.

Mr. RAIMENT (London) invited all those present who could do so to attend the meeting at Queen's Hall on Dec. 19th.

Mr. PINDER (Salford), Dr. PATTERSON (Newbury, Berks), Dr. J. STUART ROSS (Edinburgh), and Mr. C. COURTENAY LORD (Gillingham, Kent) also spoke warmly in favour of the resolution, which was then put to the vote and carried by the same overwhelming majority as the first resolution.

Sir JAMES BARR, in moving the appointment of a preliminary committee to set the new union in motion, had a somewhat mixed reception, but he pacified his audience to some extent by hearty abuse of the Bill and by a tribute to the chairman.

The meeting altogether lasted about two hours. In the confusion of departure the business of nominating and appointing the executive committee was carried out under difficulties, but those who remained seemed satisfied that their interests would be represented by those names which had been chosen.

THE PROTEST MEETING AT BIRMINGHAM.

At much shorter notice than the mass meeting at Manchester of the previous day, a large protest meeting against the treatment of medical interests under the Insurance Bill was held at the Midland Institute, Birmingham, on Friday, Dec. 15th, under the chairmanship of Mr. Frank Marsh. About 700 medical men from Birmingham and the neighbouring counties attended, and if the temper of the meeting did not exactly reflect that of the Lancashire and Cheshire audience the resolutions carried by a large majority differed little in substance or in spirit from those passed the day before. The three resolutions which were proposed from the chair were as follows:—

1. That in the opinion of this meeting of the medical profession of Birmingham and the Midland Counties the National Insurance Bill does not satisfactorily meet the just demands of the medical profession as defined in the "six cardinal points" formulated by the British Medical Association.
2. That in the opinion of this meeting the Bill will create a condition of affairs detrimental to the public interest as well as to that of the medical profession.
3. That in the opinion of this meeting the only satisfactory method of meeting the situation created by the Government is for the profession to decline to undertake any duties which the Bill proposes to assign to them.

As at Manchester, an amendment proposing that the medical profession should decline to work under the Act "unless the six cardinal points were conceded" was rejected, but this suggestion to continue the policy of the British Medical Association received more support at Birmingham than at Manchester, although the large majority voted against it.

Both the CHAIRMAN and the seconder, Dr. HOYLE WHAITE (Birmingham) disclaimed antagonism to the Association, and denied that there was any wish to cause a direct split amongst its members. Their object was to gauge the true attitude of the profession towards the Bill. They advised that the profession should make a united stand and resolutely declare that it would have nothing more to do with the Bill.

The CHAIRMAN said that any division in their ranks now would put an end to all effective opposition to the working of the Act and would simply play into the Chancellor's hand, who had already thrown a bombshell among them by a recent appointment, and had created the false impression in the public mind that the Bill in its medical aspects was acceptable to the profession. He (Mr. Marsh) rejected the idea that the Bill as enacted satisfied the six-fold requirements laid down by the Association. If they accepted service under such conditions as were imposed upon them their independence was gone, and the result would be detrimental alike to the public interest and to the interest of the medical profession. He concluded by referring to the enormous depreciation in the saleable value of working-class practices which had already occurred even before the Bill became law.

Dr. WHAITE stigmatised the Chancellor's proposal that the profession should make the best use it could of the chance he had given it of collective bargaining as an insult and an injustice.

Dr. MILNER M. MOORE, Mr. L. J. STRETTON, Dr. GARMAN, and Professor ROBERT SAUNDBY counselled against action which would bring them out of line with the policy of the Association, and Professor J. T. J. MORRISON supported Mr. Stretton's amendment to add the words which would prevent that result. Professor Saundby, as President of the British Medical Association, approved the Council's action in recommending Mr. Smith Whitaker to accept the Chancellor's offer. He, however, traced the present trouble to the weak action taken by the Representative Body in June last; the stand which was being advocated now should have been pressed for then with the same strength.

The amendment was lost, and the three-fold resolution was passed by a very large majority, thus bringing the practitioners of the Midlands into line with those of the Northern area.

THE PROTEST MEETING IN LONDON.

The mass meeting which had been arranged by Dr. F. J. Smith and an executive committee of London medical men was held in the Queen's Hall on Tuesday afternoon, Dec. 19th, and was the largest gathering of the profession which has yet been held to protest against the medical provisions of the National Insurance scheme. The chair was taken by Sir WILLIAM WATSON CHEYNE, and he was supported upon the platform, among others, by Sir William Church, Sir John Tweedy, Sir Alfred Pearce Gould, Sir William Osler, Dr. Mary Scharlieb, Mr. Brudenell Carter, Professor Howard Marsh, Dr. Sidney Phillips, and Dr. F. J. Smith. The hall was crowded, and only in the highest gallery and at the back of the platform were there any vacant seats; the total number present was well over 2000. Several representatives of the profession in Manchester were on the platform by invitation. Their words were listened to with close attention, and the oratory of Dr. T. A. Helme aroused as much enthusiasm as it had done at the mass meeting at Manchester. The feeling of this large assembly of medical practitioners was almost unanimously in favour of the resolutions proposed, and these were carried by immense majorities. It is to be regretted that Sir Victor Horsley and other apologists of the action taken by the Council of the British Medical Association met with a hostile and disorderly reception, but their presence on the platform was deeply resented by a large number of the medical practitioners present. The confusion which resulted interrupted the business of the meeting and tended to obscure that unanimity of feeling and intention which was so clearly expressed when the resolutions were proposed and submitted to the vote.

The CHAIRMAN in opening the proceedings said they had met under extraordinary and very serious circumstances. A very able and astute statesman had conceived the idea of National Insurance against sickness and unemployment, and had produced a scheme which in some points was admirable but which required careful consideration. He had offered to the public free medical attendance, and the offer had been accepted; but before very long the insured persons would be asking about the kind of medical attendance they were receiving. It was extraordinary that up to the present no definite arrangements had been made with the medical profession, which was to provide the medical attendance promised. No attempt had been made to find out under what conditions it would work, or, if this had been made, the wrong individuals had been consulted. The Chancellor of the Exchequer could not now plead ignorance of the terms under which the profession would do its part of the work. But the Act did not contain any of the demands that the profession had made. What, then, was to be done? This meeting was called in order to tell the Chancellor of the Exchequer that the profession would have no more specious promises, and that until the limited demands of the profession had been put into such a form that there could be no possible quibble, medical men would refuse to give medical treatment as laid down under the Act. There was no strike of the medical profession; they were only asking the Chancellor of the Exchequer to give them the terms which they considered just, and in the alternative they would treat the sick poor in the way they had always done. Under the existing conditions the poor were better off than they would be under the Act. If they were to carry their point they must be united. The effect of this Act would be that thousands of medical men would be reduced to a state of penury or worse. He asked them to support the British Medical Association, the only Association they had, and if fault was found with the Council to get other servants who would better serve the general wish. He begged the speakers who would follow him to avoid all personalities, and to avoid any reference to the Association which would cause its disunion.

Dr. F. J. SMITH, who was received with loud and prolonged cheering, then moved the first resolution, which read as follows:—

> That this mass meeting of the medical profession is of opinion that the six cardinal points originally formulated by the British Medical Association are not guaranteed by the provisions of the Insurance Act in a manner which satisfies the profession.

He passed in review the various provisions of the Act as they affected the medical profession, and showed that any concession that had been made to the profession with one hand the Chancellor had taken away with the other. With regard to medical representation on the Insurance Committees, he showed that it could not be more than one-eighth and possibly only one-tenth, and a section of the Act gave power to approved societies to appoint their own officers on the Committees—just the people they were trying to avoid. Then with regard to statutory recognition, the clause meant nothing, and he foresaw much wrangling with the Commissioners. Again, there was nothing to safeguard the income-limit. The £104 income-limit had not been conceded. He had been told that this limit could have been secured, but the negotiators for the medical profession had preferred to sacrifice professional interests rather than run the risk of putting the Government in danger of defeat. The profession had given to the Council a mandate to secure the six cardinal points as a minimum or to die in the last ditch.

Mr. M. MILTON TOWNSEND seconded. He said the main object of the meeting was to sign a requisition for an extraordinary meeting of the British Medical Association. If the medical profession stood firm they would be able to compel the Government either to give the profession their just demands or to drop the medical provisions of the Act. None of the cardinal points had been conceded, and it was for the meeting to say whether they considered that the demands of the profession had been embodied in the Bill.

At this point Sir VICTOR HORSLEY rose in the body of the meeting and was invited by the chairman to come up on the platform. On attempting to address the meeting he was met with great shouting and opposition, but was eventually allowed to say a few words. He said that with the general terms of the resolution he could find no fault except on the point of grammatical accuracy. The inaccuracy lay in the fact that the six cardinal points of the Association were said to have been ordered by the Representative meeting to be inserted in the Bill. That was not so. Such points as could be inserted into the Bill were to be inserted, and the others were to be settled with the Insurance Commissioners. Again there was uproar, and the meeting refused to allow the speaker to proceed further. In spite of appeals from the chairman and from various groups of the audience, Sir Victor Horsley was compelled to resume his seat.

The resolution was then put and carried with only six dissentients.

Mr. P. C. RAIMENT proposed the second resolution:—

> That this mass meeting re-asserts the fundamental importance of the demands of the medical profession, and is of opinion that every medical practitioner should refuse to accept any office for giving medical attendance and treatment to persons insured under the Act until those demands shall have been definitely conceded.

He submitted that it was not only legitimate but absolutely imperative that the boycott of the profession should continue until the Government had adopted the six cardinal points, or dropped the medical provisions of the Bill altogether. The third alternative was to allow the medical profession to make their own arrangements with the insured. The unity of the profession could best be attained and the Government be compelled to concede its demands by each individual member of the profession refusing to work under the Act.

Dr. T. A. HELME seconded. The National Insurance Bill, he said, had now become law, and in face of such a crisis this was no time for quarrelling among themselves. They were all agreed on the six points, and they would not work unless those points were conceded. The Council of the Association urged them to proceed at once to form the Local Committees and to continue negotiating and bargaining. To bargain with advantage they must stand on equal terms. On the one side there were working men with executive powers and the Commissioners, and on the other a medical body without statutory powers and with only the privilege of going on its knees and begging. The Act had passed with its Harmsworth amendment, and its framework could not now be altered. Was that what they wanted? Was club practice under lay control the fulfilment of their ideals? There was one thing on which the profession might all unite, and he was there to tell them that the men of the North desired united action for themselves and asked the men of the South to stand by them. In this way the profession would get what it wanted. They must refuse to take office as stated in the terms of the resolution. They must make known to the Commissioners their position, and so far as the medical profession was concerned the matter ended. All recognised

that there was much in the Act that was good, but the profession would not allow Mr. Lloyd George to give his charity at their expense. The medical service of the poor to be efficient must be under medical control. The Council of the British Medical Association had failed them, their confidence in it was gone. Pledges were not sufficient; a guarantee must be obtained.

Mr. G. H. PINDER supported the resolution, and said that the profession in Yorkshire, Lancashire, and Cheshire was united solidly.

Dr. BRIERLEY said that the profession must have statutory powers to carry into effect its wishes. By the Act they were asked to work contract practice under conditions of abject slavery.

Sir A. PEARCE GOULD, after an impressive plea for unity and a powerful protest against the evils of club practice, said the profession would refuse to act until their just demands had been conceded. The Act said that the Commissioners were to see that provision was made for adequate medical attention to the poor. Little had been said about remuneration, but how could that be determined until it was decided what was to be paid for? No notion had yet been given as to the character and nature of the work demanded of the profession. They all wanted to see the medical treatment of the industrial population of this country done as well as it could be done, and the medical profession properly remunerated. The new legislation was an extension of the legislation of the past century based on charity. Let them do their work as best they could, but let them insist on being paid like men.

Dr. J. H. KEAY, speaking on behalf of the Council of the Association, asked whether anyone knew of any Bill dealing with social legislation during the past 100 years in which everything had been embodied and nothing left to be fixed by Commissioners; but at this point he was interrupted and was compelled to resume his seat.

Dr. WILLIAM DOUGLAS agreed that the six cardinal points were the irreducible minimum, and claimed that the British Medical Association was using every possible means to ensure that no practitioner should undertake the medical attendance of insured persons unless absolutely in accordance with the six cardinal points of the Association.

Dr. WHEELER HART, of Manchester, said the profession never dreamed that the Council would approve of any Act of Parliament which would not guarantee that they should get the six points by statutory means. If there was to be a strike this was the issue on which it would take place. The points must be so embodied in the Act that they could be carried out by constitutional means, and by ways which were consistent with their work as professional men and gentlemen.

Before the close of the meeting Dr. SIDNEY PHILLIPS proposed that the resolutions passed with such unanimity by those present should be forwarded by the chairman to the Prime Minister and the Chancellor of the Exchequer. This was seconded by Sir JOHN TWEEDY and carried with acclamation.

On their departure members of the British Medical Association were given an opportunity of signing their names to a requisition to the Council of the Association for an extraordinary general meeting, to be held within 21 days, in accordance with the articles of the Association. This received many signatures, and has since been forwarded to the headquarters of the Association. Its wording was as follows:—

NATIONAL INSURANCE BILL.

Requisition for an Extraordinary General Meeting.

Dec. 19th, 1911.

TO THE CHAIRMAN AND COUNCIL OF THE BRITISH MEDICAL ASSOCIATION,—We, the undersigned members of the British Medical Association, hereby require the Council, in accordance with Articles 20, 21, and 22 of the Articles of Association of the British Medical Association to convene an Extraordinary General Meeting of the British Medical Association for the purpose of discussing the following resolution as special business, namely:—

That, in the opinion of this Extraordinary General Meeting of the members of the British Medical Association, the National Insurance Act does not safeguard the six cardinal points of the policy of the British Medical Association in a manner satisfactory to the members of the aforesaid Association, and we consider that the Council of the British Medical Association has failed in its duty towards its members.

Here followed the names and addresses, and the Divisions to which they belong, of the members of the Association signing the requisition.

THE COUNCIL OF THE BRITISH MEDICAL ASSOCIATION AND THE MEDICAL PROFESSION.

Sir Victor Horsley, Dr. J. H. Keay, and Dr. A. J. Rice-Oxley have addressed a letter to the *Times*, intended to define the constitutional position of the Association, which they were unable to do at the meeting in Queen's Hall, being refused a hearing. The letter contends: (1) That in dealing with the Insurance Bill the Association, through its Representatives, and not the Council, has been responsible for the policy pursued; (2) that the Council was instructed that points in the policy of the Association, if unable to be secured otherwise, should be determined by the Insurance Commissioners; (3) that with regard to the wage-limit, the Representatives found that it was impossible to fix either a flat rate or a common method of remuneration; and (4) that "free choice of doctor," owing to amendment of the Harmsworth amendment at the instigation of the Council, was provided for in the Act.

A PROTEST MEETING AT SHEFFIELD.

A large number of Sheffield medical men, nearly 300 in number, met on Tuesday last and protested almost unanimously against the conditions of the Act. Mr. Archibald Cuff, who presided, said that if the profession accepted less than the minimum demands which they had formulated they would sacrifice their whole position, professional and financial. Mr. Lloyd George had made concessions, but these had been nullified by other concessions. Their leaders had capitulated too easily and accepted these trifling concessions when a bolder course would have been better. Neither the House of Commons nor the public had believed that they were in earnest.

A resolution was proposed refusing to form a panel under the Act or to undertake any duties which it proposes to assign to the profession. An amendment in favour of refusing to enter into arrangements for the treatment of insured persons on terms inconsistent with the declared policy of the British Medical Association was defeated, only five voting for it. The resolution was then carried.

THE SCOTTISH COMMISSIONERS.

The appointment of the following Scottish Commissioners under the National Insurance Act is officially announced:—

Chairman:—Mr. James Leishman, Treasurer of the City of Edinburgh.

Deputy Chairman:—Dr. John Christie McVail, M.D., LL.D.

Commissioners:—Mr. John McNicol, General Secretary, Loyal Order of Ancient Shepherds, Ashton Unity; and Miss M. M. Paterson, H.M. Deputy Principal Lady Inspector of Factories.

Secretary:—Mr. John Jeffrey, Inspecting Officer, Local Government Board for Scotland.

THE WELSH COMMISSIONERS.

The Welsh Commissioners have been announced as follows:—

Chairman:—Alderman T. J. Hughes, Vice-Chairman of the Glamorgan County Council.

Commissioners:—Dr. Meredith Richards, Medical Officer of Health of Croydon; Mr. J. Rowland, M.V.O.; and Hon. Violet Douglas-Pennant.

Secretary:—Professor T. Jones.

"ENEMIES OF THEIR PROFESSION."

To the Editor of THE LANCET.

SIR,—In an unfortunate moment I agreed, at the request of the honorary secretary of the Marylebone Division, who was going for a holiday, to undertake a postal canvas of the medical practitioners resident in the division asking them (1) to sign an "undertaking"; (2) to give a "guarantee";

and (3) inviting those who were not members of the Association to become so. The honorary secretary of the division had been requested by the late medical secretary of the Association to carry out this canvas. I should not have thought it possible to call forth so much personal abuse in such a little time, and it is quite evident that there is a large number of medical men in the division at the present time in a peculiarly irritable condition.

The following is a fair specimen of a large number of communications I have received during the last few days by post and telephone :—

I consider it extremely offensive on your part to send me a circular in which you threaten me that the profession to which we both have the honour to belong will "regard those who after repeated applications persist in refusing to commit themselves to a definite statement on behalf of the profession's policy as being, however unintentionally, enemies of their profession."

The statement between the inverted commas is abstracted from the fourth paragraph of Circular 3 issued with the sanction of the Council of the Association, one of the documents I was requested to circulate. I understand that a great many members of the medical profession residing in the Marylebone division are holding me personally responsible for what they are pleased to term this "offensive paragraph," and so, with your permission, I hasten to deny the soft impeachment of being a "blackmailer," and to disassociate myself with, to say the least of it, such unfortunate phraseology as is to be found at the end of this fourth paragraph of Circular 3.

I signed Circular 3 as an officer of the Association, but also as one who had no control over the actions of the Council or of the late medical secretary. I wish I had!

I am, Sir, yours faithfully,

Wimpole-street, W., Dec. 19th, 1911. COMYNS BERKELEY.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—As the result of the recent Final Fellowship Examination held on Nov. 23rd, 27th, 28th, 29th, 30th, and Dec. 1st, for which 72 candidates presented themselves, of whom 33 were approved and 39 were rejected, the council at its meeting on Dec. 14th conferred the Diploma of Fellow upon 31 candidates (including one lady—Miss Eleanor Davies-Colley, M.D., B.S. Lond., Royal Free Hospital—the first lady to obtain the Fellowship). The following are the names of the successful candidates :—

Harry Robinson, M.R.C.S., L.R.C.P., St. Bartholomew's Hospital; Thomas Waddelow Smith, M.R.C.S., L.R.C.P., L.S.A., King's College Hospital; Alfred John Hull, Captain R.A.M.C., M.R.C.S., L.R.C.P., Guy's Hospital; Arthur Charles Haslam, M.D., B.S. Lond., M.R.C.S., L.R.C.P., St. Thomas's and St. Bartholomew's Hospitals; Harold Rowe Jeremy, M.R.C.S., L.R.C.P., London and St. Bartholomew's Hospitals; Henry Lewis Morgan, M.B., B.S. Lond., M.R.C.S., L.R.C.P., London Hospital; James Richard Henry Turton, M.B., B.S. Lond., M.R.C.S., L.R.C.P., St. Bartholomew's and St. George's Hospitals; Gathorne Robert Girdlestone, M.B., Ch.B.Oxon., M.R.C.S., L.R.C.P., Oxford University and St. Thomas's Hospital; Alexander Todd McCaw, M.R.C.S., L.R.C.P., London Hospital; Bertram Arthur Lloyd, M.B., B.S. Lond., M.R.C.S., L.R.C.P., Birmingham University and London Hospital; David Ranken, M.B., B.S. Lond. and Durh., M.R.C.S., L.R.C.P., Durham University and St. Bartholomew's Hospital; Philip Alfred Reckless, M.R.C.S., L.R.C.P., St. Bartholomew's Hospital; Lionel Colledge, M.A., M.B., B.C. Cantab., M.R.C.S., L.R.C.P., Cambridge University and St. George's Hospital; Habibmia Ismail Janmahomed, M.D., B.S. Lond., M.R.C.S., L.R.C.P., and Vincent Townrow, M.B., B.S. Lond., M.R.C.S., L.R.C.P., Guy's Hospital; Bernard Grainger Goodwin, M.R.C.S., L.R.C.P., Birmingham University and London Hospital; Harry Lee, M.B., B.C. Cantab., M.R.C.S., L.R.C.P., Cambridge University and Guy's Hospital; William Robert Parkinson, M.R.C.S., L.R.C.P., St. Thomas's Hospital; Samuel Ariaratnapillai Vairakiam, L.M.S. Ceylon, M.R.C.S., L.R.C.P., Ceylon Medical College and London Hospital; Wilfrid Langrish Pink, M.B., B.S. Lond., M.R.C.S., L.R.C.P., St. Thomas's Hospital; Andrew Samuel Moorhead, M.B. Toronto, M.R.C.S., L.R.C.P., Toronto University and London and Middlesex Hospitals; Aleck William Bourne, B.A., B.C. Cantab., M.R.C.S., L.R.C.P., St. Mary's Hospital; Howard Bullock, M.B., Ch.M. Sydney, M.R.C.S., L.R.C.P., Sydney and Oxford Universities and London Hospital; Casement Gordon Aickin, M.B., Ch.B. New Zealand, Otago University and St. Bartholomew's Hospital; James Harris Connolly, M.B., Ch.B., M.D. Edin., Edinburgh University, St. Bartholomew's and Middlesex Hospitals; Eleanor Davies-Colley, M.D., B.S. Lond., Royal Free Hospital; Henry Mulrea Johnston, B.A., M.B. R.U.I., Queen's College, Belfast, Dublin University, and St. Bartholomew's Hospital; Alfred Fay Maclure, M.D., B.S. Melbourne, Melbourne University and Middlesex Hospital; Robert Charles MacWatt, M.B., C.M., B.Sc. Edin. (Lieutenant-Colonel, I.M.S.), Edinburgh University and London Hospital; Charles Gordon Shaw, M.D., B.S. Melbourne, Melbourne University and Middlesex and St. Mary's Hospitals; and Thomas Wingate Todd, M.B., Ch.B. Manchester, Manchester University.

The following gentlemen successfully passed the examination but are not eligible to receive the Fellowship because they have not yet attained the requisite age of 25 years :—

Robert Coltart Harkness, M.B., Ch.B. Edin., M.R.C.S., L.R.C.P., Edinburgh University and St. Bartholomew's Hospital; Arthur Gordon Haynes Lovell, M.B., B.S. Lond., M.R.C.S., L.R.C.P., St. Mary's Hospital; and Bernard Constable Maybury, M.B., B.S. Lond., M.R.C.S., L.R.C.P., St. Thomas's Hospital.

Licences to practise Dentistry were also conferred upon the undermentioned 44 gentlemen who have complied with the by-laws :—

Eric Bernard Armitage, Middlesex and Royal Dental Hospitals; Norman Arthur Austin, Birmingham University; Ernest Walter Bacon and Edwin Randolph Bailey, Guy's Hospital; Alfred Barritt, Middlesex and National Dental Hospitals; Victor Emmanuel Dawson Bergh, Guy's Hospital; John William Bowen, St. Bartholomew's and Royal Dental Hospitals; Henry James Burch, Guy's Hospital; Arthur Caspar Stevenson Cottam and James Kenneth Crawford, Charing Cross and Royal Dental Hospitals; Philip Percival Davies, Middlesex and National Dental Hospitals; Thomas Clement Davies, Charing Cross and Royal Dental Hospitals; Harold Graham Elliott and Reginald Gilbert Farrington, Guy's Hospital; Edwin Joseph Handford, Bristol University; Harold Harvey, Birmingham University; John Otway Hayes, Middlesex and National Dental Hospitals; Ernest Victor Jones, Charing Cross and Royal Dental Hospitals; Michael William Joseph Davis Joseph, Birmingham University; William Symons Lakeman, Guy's Hospital; Harold Lionel Laws, B.A. Oxon., M.R.C.S., L.R.C.P., St. George's and National Dental Hospitals; Frank Lodge, Charing Cross and Royal Dental Hospitals; Harold Leonard Meyer and Raphael Neft, Guy's Hospital; Thomas Spencer Osmer, Middlesex and Royal Dental Hospitals; Jal Framji Patel, L.M.S. Bombay, Bombay University and Guy's Hospital; Percy John Peatfield, Guy's Hospital; Felix Lambert Pradier, Middlesex and National Dental Hospitals; John Griffith Richards, Guy's Hospital; Warren Longtoft Roberts, Leeds University; Russell Rodgers and John Hampden Ross, Guy's Hospital; Robert Dendy Sadler, Middlesex, Royal, and National Dental Hospitals; Isidore Gittleson Samuels and Hubert Dennis Shore, Guy's Hospital; William Christie Tattersall, Middlesex and National Dental Hospitals; Thomas Reginald Trounce, Walter Colin Wade, Douglas Wain, Frank Roland Wallis, and Clifford Toulson Watson, Guy's Hospital; William Henry Whitworth, Manchester University; Charles Henry Wilson, Bristol University; and Henry Stanley Young, St. Thomas's and Royal Dental Hospitals.

UNIVERSITY OF LIVERPOOL.—The Diploma in Tropical Medicine has been awarded to the following :—

F. F. Brown, M.D., C.M. McGill; D. J. Chand, L.R.C.P. & S. Edin., L.F.P.S. Glasg.; J. M. Holmes, B.A., M.B., B.Ch., B.A.O. Dub.; C. L. Ievers, L.R.C.P. & S. Edin., L.F.P.S. Glasg.; E. K. Lomas, M.B., Ch.B. Manch.; D. S. MacKnight, M.B., Ch.B. Edin.; J. V. Mascarenhas, M.B., C.M. Madras; A. L. Oluwole, M.B., Ch.B.; and J. A. Taylor, M.B., Ch.B. Edin.

At examinations held recently the following candidates were successful :—

DEGREES OF M.B. AND CH.B.

Second Examination.—Part A, Ethel Chadwick, G. H. Darlington, A. N. Misbah, G. H. Pearson, L. B. Stott, and A. W. Weston. Part B, F. A. Belam, C. W. Dixon, H. E. Marsden, R. Martlew, A. C. Mooney, and R. E. Roberts.

Final Examination.—Part I.: Kate M. Cowe, D. Parkes, H. P. C. de Silva, and T. O. Williams. Part II.: D. Parkes.

DIPLOMA IN DENTAL SURGERY.

Third Examination.—A. E. Bate.

THE INSURANCE ACT AND NURSES.—At a general meeting of the Midland Association of Matrons and Lady Superintendents (Warwickshire, Worcestershire, and Staffordshire) the following resolutions were unanimously carried :—

That the Midland Association of Matrons and Lady Superintendents in general meeting assembled, seeing that under Clause 17 (or 20) of the National Insurance Bill nurses may be appointed to attend on insured persons, are gravely concerned that thereby recognition by the State of untrained or partly trained nurses may follow, and they consider that such recognition must inevitably lead to deterioration of the standard of nursing profession. The Midland Association of Matrons and Lady Superintendents strongly urge, therefore, that the words "fully trained" be inserted before the words "district nurse" and "nurse" in Clause 17 (or 20).

That the Midland Association of Matrons and Lady Superintendents beg that a thoroughly trained nurse may be placed upon the Advisory Committee to be nominated by the Insurance Commissioners under the National Insurance Bill.

REMARKABLE STATISTICS REGARDING DEFECTIVE EYESIGHT.—The Lambeth board of guardians, at its last meeting, considered a return showing that in 12 months 632 visits were made by children in the Poor-law schools at Norwood to the Royal Eye Hospital. The medical officer reported that each child sent to the institution was suffering from defective vision and in need of treatment by a specialist. No less than 122 pairs of spectacles had been provided, costing £20 9*s.* 6*d.*, whilst repairs were executed amounting to £12 17*s.* 6*d.* The travelling expenses to and

from the hospital were £21 1*s.* 5*d.* There were 70 girls and 58 boys in the school wearing spectacles, the proportion being somewhat in excess of 20 per cent. of the school population. The board decided in future to send the children for treatment in regard to their eyes to the clinic established by the London County Council at Chestnut-road, West Norwood.

ROYAL INSTITUTION.—The annual Christmas course of juvenile lectures at the Royal Institution begins on Dec. 28th at 3 o'clock, when Dr. Chalmers Mitchell will deliver the first of six lectures on the Childhood of Animals.

His Excellency the Viceroy and Governor-General of India has appointed Brevet-Colonel R. H. Firth, R.A.M.C., to his personal staff as honorary surgeon, from Nov. 3rd, 1911, *vice* Colonel R. H. Forman, retired.

LITERARY INTELLIGENCE.—The first volume of "A New System of Surgery," of which the general editor is Mr. C. C. Choyce, F.R.C.S. Eng., and the pathological editor Professor J. Martin Beattie, M.D. Edin., is announced for early publication by Messrs. Cassell and Company.

AT a meeting of the Senate of the University of London on Dec. 13th the Royal Dental Hospital and London School of Dental Surgery was admitted as a School of the University in the Faculty of Medicine (in dentistry only) for a period of five years as from Oct. 1st last.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The National Insurance Act.

THE National Insurance Bill became an Act of Parliament on Saturday, Dec. 16th, when it received the Royal Assent. The alterations made in the measure in the House of Lords were numerous, but for the most part they were intended merely to improve the drafting of the Bill. Their effect on the provisions of the Bill as it left the House of Commons is small. For instance, the designation "Local Health Committee" has been changed to "Insurance Committee." The official Opposition in the House of Lords adhered to its intention expressed by the Marquis of LANSDOWNE on the second reading, and refrained from any attempt to examine or reframe the provisions of the measure. The attitude of the Opposition was that at this period of the session it was impossible to undertake the systematic review of a Bill so complex and lengthy, and that the Government must accept the entire responsibility for it. It is common ground to politicians of all parties that the details of the Act are so complicated, and the varieties of circumstance which they have to meet are so numerous, that amending Bills will be necessary as experience reveals the weak points.

The Medical Profession and the Insurance Act.

Some references to the position of the medical profession under the National Insurance legislation of the Government were inevitable during its passage through the House of Lords. When the measure was in Committee on Thursday, Dec. 14th, the Bishop of BANGOR proposed to introduce into Clause 15 (administration of medical benefit) a provision giving to medical practitioners who had been struck off the panels the right of an appeal to the General Council of Medical Education and Registration. Viscount HALDANE, who had charge of the Bill in the House of Lords, resisted the amendment, arguing that the powers given to the Insurance Commissioners to revise such removals were adequate. The amendment was negatived without a division. Speaking on Clause 15, Viscount MIDLETON made some criticism on its effect. He feared that the general extension of contract practice would make intolerable demands on the medical profession, for which the scale of remuneration contemplated by the Chancellor of the Exchequer and his advisers was quite inadequate. When persons might call in a medical men without having to pay for his visits, many would ask for medical attendance who now went without it. Viscount HALDANE'S answer was that he did not think any difficulty would arise in getting doctors to do the work. It was often extremely difficult for young medical men to secure a start in their profession; but if they got their names placed upon the panel the Bill would give them an opportunity which they had not at present.

The attitude of hostility of the medical profession, particularly in the North of England, to the terms offered to them under the National Insurance Act has caused some apprehensions in Ministerial quarters at Westminster. The spokesmen of the Government have expressed a "hope" that the difficulties with the profession will be removed by the regulations issued by the Insurance Commissioners and by the negotiations conducted in each locality. Lord ASHBOURNE, on Friday Dec. 15th, put a question to the Government on the attitude of the medical profession. Viscount HALDANE was absent from his place when the question was put, but Earl BEAUCHAMP replied that the Government hoped that the medical men would be willing and ready to work the Bill. In expressing this view he admitted that he had read the report of the Manchester meeting held on the previous day.

The Prorogation.

On Saturday, Dec. 16th, Parliament was prorogued until Wednesday, Feb. 14th. Among the measures to receive the Royal Assent was the Rag Flock Act.

HOUSE OF COMMONS.

WEDNESDAY, DEC. 13TH.

Sleeping Sickness.

Dr. CHAPPLE asked the Secretary of State for the Colonies whether the evidence that glossina morsitans was a carrier of the trypanosome of sleeping sickness was now sufficiently conclusive to justify him in so relaxing the severity of the game laws of Nyassaland as to permit of the natives hunting game known to harbour the trypanosome in their blood, in order that both the game and the infecting fly which invariably accompanied it might be driven off from the populous centres and the black and the European population and their domestic animals be protected from the spread of this disease.—Mr. L. HARCOURT replied: There is not yet sufficiently conclusive evidence to justify my taking the course suggested. A scientific Commission, under the direction of Colonel Sir David Bruce, is now engaged in investigating in the Protectorate the relations between the fauna of the country, the tsetse fly, and the trypanosome, and when definite results are reached I shall not hesitate to adopt such measures as may be required. It must be remembered that domestic animals as well as game are suspected of being carriers of the trypanosome.

Dr. CHAPPLE: Is the right honourable gentleman not aware that sleeping sickness in man and trypanosomiasis in domestic animals are spreading in Nyassaland, and that these are associated with the presence of game and tsetse around the populous centres?—Mr. L. HARCOURT: I have been in close communication with Dr. Kinghorn, and I am considering the matter very carefully. Whilst the Commission is inquiring into it I think I ought to be allowed to wait for their recommendations.

Dr. CHAPPLE: Is the right honourable gentleman aware that in the meantime sleeping sickness is spreading very rapidly in Nyassaland, and that Professor Koch recommended that the game be driven back from populous centres because of the danger to natives and domestic animals from the proximity of game and infective tsetse, and is it not a fact that Dr. Kinghorn has experimentally inoculated susceptible animals with trypanosomiasis from the bite of infected glossina morsitans, the tsetse fly of Nyassaland?

The SPEAKER: The honourable Member can hardly expect the Secretary for the Colonies to answer those matters without notice.

Dr. CHAPPLE subsequently, on the motion for the adjournment, called attention to the immediate importance of doing something with regard to the spread of sleeping sickness in Nyassaland. There was, he said, a great waste of precious time involved in waiting for the report of the Sleeping Sickness Commission, while in the meantime the disease was spreading amongst the natives and the whites and also amongst the domestic animals. A number of whites as well as natives had been dying in Nyassaland from sleeping sickness. A report had just come to hand from Nyassaland in which the following sentence occurred: "The health of the native community has been quite satisfactory apart from the existence of sleeping sickness, which has slowly been extending during the last 12 months in spite of every effort to arrest it." The honourable Member was proceeding to discuss the relation of the disease to domestic animals when the House was "counted out" owing to the absence of a quorum.

The Insurance Bill and Medical Benefit.

Mr. NORMAN CRAIG asked the Secretary to the Treasury whether any and, if so, what steps would be taken to ensure that, in the event of the National Insurance Bill becoming law, insured persons would receive the medical benefit purported to be secured to them by the Bill.—Mr. MCKINNON WOOD replied: I trust that no difficulties will arise in this respect, but I can assure the honourable Member that if they should arise adequate steps will be taken to deal with them.

Patent Medicines.

Mr. LYNCH asked the Secretary of State for the Home Department whether, in regard to the Select Committee to consider medical matters, he would consider the advisability of making the terms of reference fairly extensive, so that not merely questions of patent medicines might be dealt with, but also the practice of medicine by unqualified men.—Mr. MCKENNA replied: I do not think it would be wise to extend the scope of the inquiry beyond patent medicines.

Mr. LYNCH asked the right honourable gentleman whether he was in a position to state whether the Select Committee promised for next session to inquire into the subject of patent medicines and allied matters would be a departmental committee or in the nature of a Royal Commission; and whether the medical profession would be represented both in regard to science and to professional practice.—Mr. MCKENNA answered: I am unable at present to make a definite announcement, but it is proposed that the inquiry should be by a Select Committee of this House or possibly a joint Select Committee.

THURSDAY, DEC. 14TH.

Anthrax.

Mr. JOWETT asked the Secretary of State for the Home Department whether he would say how many cases of internal anthrax had occurred during the 10 years commencing Jan. 1st, 1900, in establishments where woolcombing regulations were in force, and how many of these were fatal.—Mr. MCKENNA answered: The number of reported cases of internal anthrax in woolcombing establishments during the 10 years 1901 to 1910 was 18, of which 17 were fatal.

Mr. JOWETT also asked the right honourable gentleman whether he would state how many cases of internal anthrax occurred among woolsorters during the 10 years immediately preceding the one in which the woolsorters' regulations, issued in 1897, were put into force, and

how many were fatal, and the number of cases of internal anthrax among woolsorters during the last ten years, and how many of these were fatal.—Mr. MCKENNA said, in reply: The number of reported cases of internal anthrax among woolsorters during the 10 years 1901 to 1910 was five, of which all were fatal. One case, which was also fatal, has occurred during the present year. The figures for the 10 years preceding the special rules cannot be given, as the obligation to notify cases was not imposed until 1896. I am advised, however, that such evidence as there is points to the greater prevalence of the disease then than now.

Mr. LYNCH: Is the right honourable gentleman aware that under proper conditions, which are possible, the mortality from anthrax should be reduced to nil?

Mr. MCKENNA: I believe that every precaution that can be taken is taken now, but perhaps the honourable gentleman will communicate with the Home Office what the proper precautions should be. I shall be very glad to consider them.

Mr. LYNCH: In other countries it has been so reduced.

Sanatorium Funds.

Mr. HICKS-BEACH asked the Chancellor of the Exchequer whether any of the sums available under the National Insurance Bill or the Finance Bill, 1911, for the purposes of the provision of sanatoria could be allocated towards the cost of Poor-law institutions which had been, or were being, or might be, provided for the treatment of tuberculosis. —Mr. LLOYD GEORGE wrote in reply: The answer is in the negative.

The Certification of Lunatics.

Captain FABER asked the Home Secretary whether, looking at a recent case in which a doctor refused to allow a man to be removed to an asylum owing to weakness, although he had himself certified the man insane, he would consider the advisability of preventing any local authority from appointing only one doctor to certify lunatics; and whether the Local Government Board or the Lunacy Commissioners had any power over a single doctor and were able to call in another doctor, if necessary.—Mr. MCKENNA wrote in reply: A local authority has no power to appoint any doctor to certify lunatics for reception into asylums; it rests with the justice who makes the order under Section 16 of the Lunacy Act, 1890, to call in any medical practitioner whom he may choose to examine the patient and sign the certificate. Neither the Local Government Board nor the Lunacy Commissioners have any power over the doctor who has given a certificate under Section 19 (2) for the suspension of removal, nor are they able to call in another doctor.

Vision Tests.

Mr. LYNCH asked the President of the Board of Trade whether, in reference to the various offices under his control, he could state what proportion of candidates tested for vision were colour blind; whether any classification of results was obtainable, as, for instance, with regard to degree or kind of colour blindness, or the association of this defect with any other physical condition; and, if so, whether he could give the statistics for the last five years, supplemented by any comments of the medical authorities which might be useful in the scientific regard of the question.—Mr. S. BUXTON furnished the following written reply: The only examinations in colour vision conducted by the Board of Trade are those for persons serving, or intending to serve, in the Mercantile Marine or in the fishing industry. Particulars of these examinations are published in an annual report on the sight tests, a copy of the latest issue of which I am sending to my honourable friend. As candidates for certificates of competency are required to undergo the sight tests on every occasion on which they present themselves for examination, many persons appear more than once in the total number of examinations, and the figures are therefore no guide to the general incidence of colour blindness. I am not aware of any data showing the association of colour blindness with any other physical condition, but information is available as to the nature of the colour defects of candidates who fail to pass the tests. These are classified on the Young-Helmholtz theory of colour vision, according to whether complete or incomplete red or green blindness is present. The whole question of the sight tests at present in force is now being considered by a departmental committee. A table giving the statistics desired by my honourable friend is appended:—

—	1906.	1907.	1908.	1909.	1910.
Number of examinations in colour vision	6410	6564	6288	6028	7393
Number of failures	57	76	44	71	112
Nature of defects:					
Complete red blindness	10	29	15	20	32
Incomplete red blindness	9	5	4	15	17
Complete green blindness	25	31	18	23	42
Incomplete green blindness	13	11	7	13	21

SATURDAY, DEC. 16TH.

Welsh Insurance Commissioners.

In answer to Mr. ELLIS GRIFFITH, Mr. LLOYD GEORGE said that the names of the Insurance Commissioners for Wales under the National Insurance Bill were:—Chairman, Alderman T. J. Hughes, Vice-Chairman Glamorgan county council, who for 12 years had been chairman of the financial committee of the council; Commissioners: Dr. Meredith Richards, medical officer of health, Croydon, who had had a large and varied experience of all kinds of medical work; Mr. John Rowland, M.V.O., of the Treasury; and Miss Violet Douglas-Pennant, who had had wide experience of social work; Secretary, Professor Thomas Jones, M.A., secretary of the King Edward VII. Welsh National Memorial Fund.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

HEALTH STATISTICS OF SWAZILAND.

THE annual report of the Resident Commissioner, just issued from the Colonial Office, states that the population, as shown by the Census taken in May, 1911, consisted of 1083 whites and 98,876 coloured. From 7000 to 10,000 Swazis are, however, always absent at work in the Transvaal Province. In the year ending March 31st, 1911, there were amongst the Europeans 32 births (29·54 per 1000; and 18 deaths (16·62 per 1000); the births and deaths of natives are not registered. The public health was good. Malaria is always present in the low-lying parts of the country during the rainy season; it is, however, of a mild type. In ordinary seasons fatal cases are very rare. The Government has distributed pamphlets and posters dealing with the causes and prevention of malaria. Diphtheria and whooping-cough appeared amongst European children in the Hlatikulu district, resulting fatally in a few cases. Syphilis is very common amongst the natives, and three cases of leprosy were reported. No small-pox outbreaks occurred and no vaccination was done. The Administration issues to native applicants free medicines, but on the whole they prefer treatment by the native doctors. The climate generally is mild and healthy, except in what is known as the low veld, which is malarial during the rainy season. The average rainfall for the year was 48·08 inches, as compared with 41·20, the mean for the previous five years. The hospital at Mbabane is the only Government institution in the territory. It contains one European ward and two native wards. Sixty-five patients were admitted during the year.

MEDICAL MISSION EXHIBITION.

UNDER the auspices of the Society for the Propagation of the Gospel in Foreign Parts a very interesting and successful exhibition has been held in Manchester during the past few days. The exhibition was admirably arranged to show medical wards, dispensaries, and operating-theatres that are at present in use in India, China, Burma, South Africa, and elsewhere, while there were exhibitions also of various missions in foreign parts. One of the special features of the exhibition was a valuable exhibit kindly lent by the Liverpool School of Tropical Medicine. Professor Sir Ronald Ross, of Liverpool, in opening the exhibition, delivered an interesting address on the origin of medicine in Ancient Egypt, where the medical profession and the Church were not only associated, but were one; indeed, there is evidence to show that the priests carried on researches into diseases and obtained knowledge which we had, he said, only recently re-discovered. Probably one of their most wonderful discoveries was that the effect of the venom of a serpent could be neutralised by the bite of a venomous serpent. They also knew the relation of the rat to the plague. In his opinion the ideal missionary must be both a priest and a medical man, and the Liverpool School of Tropical Medicine was intimately associated with medical missions, and many of their students had become medical missionaries. Medical missions led the way, civilisation came afterwards.

A FOOT-STRAP FOR BLISTERED FEET.

THE Army Council has issued a circular memorandum regarding a foot-strap for use by soldiers suffering from sore or blistered feet when marching. The device consists of a strap which can be fixed in a figure of 8 round the boot and is broadened at certain points of contact. When a man develops a blister or rubbed foot he puts on the strap, which, on being tightened, fixes the boot, prevents further rubbing, and changes the points of contact where there is pressure. It is claimed that the soldier can then continue to march without pain and that the constriction of the superficial blood-vessels tends to aid the healing of the blister. It is not proposed to supply these straps officially, but the Army Council has no objection to officers and other ranks making use of them should they desire to do so.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

THE following Congresses, Conferences, and Exhibitions are announced for 1911:—

Dec. 19th-23rd (Moscow).—Third Pan-Russian Therapeutical Congress.
,, 27th-30th (Baltimore).—American Physiological Society.

In 1912:—

Jan. 20th-27th (Hong-Kong).—Second Biennial Congress of the Far Eastern Association of Tropical Medicine.
Feb. 13th-14th (London).—Central Poor-Law Conference.
March 7th-11th (Berlin).—Thirty-third Balneological Congress.
March 23rd-April 4th (London, Royal Agricultural Hall).—International Smoke Abatement Exhibition.
,, (London).—First Congress of Pure Food and Health Society of Great Britain.
April 1st-7th (Tunis).—Twenty-second Congress of French-speaking Alienists and Neurologists.
,, 14th-20th (Rome).—Seventh International Congress on Tuberculosis.
,, 15th-18th (Wiesbaden).—Twenty-ninth German Congress for Internal Medicine.
,, (Rome).—Seventh International Congress of Dermatology and Syphilology.
,, (Giessen).—Congress on Study of Families, Inheritance, and Race Hygiene.
Spring (London).—Second Optical Convention.
May 7th-17th (Washington).—Ninth International Red Cross Conference.
,, 27th-June 1st (London).—Eighteenth International Congress of Americanists.
,, (London).—International Horticultural Exhibition.
June 24th-27th (London).—The (Biennial) Health Conference and Exhibition.
,, (London).—Missionary Exhibition.

SATURDAY (30th).—Royal Free (9A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.), Hospital operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

The following journals, magazines, &c., have been received:—
Revue de Chirurgie, South African Record, Journal of Tropical Medicine and Hygiene, Archives Générales de Médecine, Annali dell Istituto Maragliano, American Medicine, Birmingham Medical Review, Revue de Médecine, Therapist, Local Government Review, Bulletin of the Johns Hopkins Hospital, American Journal of Clinical Medicine, American Journal of Surgery, Journal of Obstetrics and Gynæcology of the British Empire, Nordiskt Medicinskt Arkiv, Nation in Arms, Annales des Maladies des Organes Génito-Urinaires, Archives de Médecine et de Pharmacie Militaires.

Communications, Letters, &c., have been received from—

A.—Messrs. Allen and Hanburys, Lond.; Mr. J. Astier, Asnières; Australian Book Co., Lond.; Dr. Johnston Abraham, Lond.; Army and Navy Male Nurses' Co-operation, Lond., Secretary of; Anglo-American Pharmaceutical Co., Lond.; Dr. R. Ackerley, Helouan; Mr. R. J. Albery, Lond.

B.—Dr. G. S. Blandy, St. Albans; Birkenhead Borough Hospital, Secretary of; Bayer Co., Lond.; *Birmingham Daily Post*, Manager of; Bermondsey Corporation, Medical Officer of Health of; Staff-Surgeon B. Browning, Sidmouth; Mr. W. E. Brown, Uxbridge; Dr. A. Grainger Bisset, Rothes; Berry-White Medical School, Dibrugar, Superintendent of; *British Journal of Nursing*, Lond., Editor of; Major G. Bray, R.A.M.C., Maidstone; Dr. W. E. Barton, Lond.; Dr. T. W. Bartlett, Steeple Bumpstead; Dr. Stanley Bott, Lond.; Messrs. Burroughs, Wellcome, and Co., Lond.; Messrs. Butterworth and Co., Lond.; Dr. G. Blacker, Lond.

C.—Mr. H. A. Collins, Lond.; Messrs. Condy and Mitchell, Lond.; Mrs. Charlesworth, Chislehurst; C. H. W.; Dr. J. Cropper, Chepstow; Dr. L. B. Couch, Nysack; Children's Sanatorium (Holt), Lond., Hon. Secretary of; Mr. W. B. Croskey, Eckington; Dr. I. D. Chepmell, Worthing; Messrs. Cassell and Co., Lond.; Clerical, Medical, and General Life Assurance Society, Lond.; Dr. H. P. Cholmeley, Westerham; Dr. E. J. Cooke, Sheffield; Clapton Park Photo Co., Lond.; Captain B. Churchill, R.A.M.C., Meiktila; Messrs. A. H. Cox and Co., Brighton; Messrs. J. and A. Churchill, Lond.; Messrs. T. Christy and Co., Lond.; Messrs. Constable and Co., Lond.; Church Missionary Society, Lond., Medical Committee of, Secretary of.

D.—Messrs. Davies and Co., Lond.; Messrs. Defries, Lond.; Mr. Henry George Dixon, Lond.; Mr. J. J. F. Dunn, Mussourie; Captain C. L. Dunn, Shahdara; Messrs. Dawson and Sons, Lond.; Lieutenant-Colonel D. Donovan, I.M.S., Madras; Dr. Andrew Dunlop, St. Heliers; Dr. Kenelm H. Digby, Bowdon.

E.—A. R. Elliott Publishing Co., New York.

F.—Mrs. Fyson, Mildenhall; Mr. C. F. France, Wigan; Rt. Hon. R. Farquharson, Aboyne; Miss Forrest, Motherwell; Dr. Wm. Forrest, Newbottle; Messrs. Fairchild Bros. and Foster, Lond.; Messrs. Fallows and Co., Birmingham.

G.—Dr. J. B. Giles, Middlesbrough; Mr. E. Gane, Ryhope; Messrs. C. T. Gettings and Sons, Lond.; Mr. H. B. Greene, Lond.; Dr. J. Ganner, Acocks Green; Messrs. Gould and Portmans, Lond.; Grimsby and District Hospital, Secretary of; Mr. E. W. Hey Groves, Clifton.

H.—Mr. W. A. Higgs, Castle Coombe; Dr. E. J. F. Hardenberg, Chingford; Messrs. Hardy and Co., Manchester; Dr. W. Jobson Horne, Lond.; Harrod's Limited, Lond., Advertisement Manager of; Dr. J. M. Hobson, Croydon; Dr. Bernard Holländer, Lond.; Mr. J. J. Hemming, Margate; Mrs. Hall, Barnet; Dr. F. Hare, Lond.; Mr. T. H. Hewitt, Lond.; Dr. R. Heilbrun, Berlin; Messrs. C. J. Hewlett and Son, Lond.

I.—Irish Literary Society, Lond.

J.—Mr. H. W. Jackson, Lond.; Dr. J. G. Jisr, Acre; J. R. F.

K.—Messrs. D. J. Keyner and Co., Lond.; Messrs. Kutnow and Co., Lond.; Professor A. Keith, Lond.; Mr. P. E. Kingsford, Ellesmere Port; Dr. W. B. Kendall, Gravenhurst; Dr. Knight, Edinburgh; Dr. C. F. Knight, Edinburgh; Dr. Leonard Kidd, Lond.

L.—Liquid Veneer Co., Lond.; Messrs. Lee and Nightingale, Liverpool; Liverpool Medical Institution, Librarian to the; Mr. C. Lillingston, Gorleston; Dr. T. C. Leman, Chipping Sodbury; Leicester Infirmary, House Governor and Secretary of; Mr. H. K. Lewis, Lond.; Rev. E. Lacon, Seaton; Mr. H. Littlewood, Leeds.

M.—Messrs. Marston, Thompson, and Evershed, Burton-on-Trent; Messrs. Masson and Co., Paris; Captain McCarrison I.M.S., Lond.; Mr. R. Mosse, Berlin; Mr. R. H. Marquis, Lond.; Dr. Egbert C. Morland, Arosa; Dr. G. Madden, Lond.; M. B.; Messrs. H. Muller and Co., Lond., Messrs. Maclehose and Sons, Glasgow; Messrs. Meister, Lucius, and Brüning, Lond.; Dr W. A. Milne, Lond.; Mr. S. C. H. Moberly, Winslow; M. W., Newcastle-on-Tyne; Mr. E. Merck, Lond.; Medical Defence Union, Lond.; Marris Products Co., Lond.; Miss M. Mollett, Lond.; Sir Robert Morant, Lond.; Dr. Moraes Manchego, Lisbon.

N.—Mr. J. C. Needes, Lond.; Mr. H. Needes, Lond.; Captain V. B. Nesfield, I.M.S., Ghaziabad; Northumberland and Durham Medical Society, Newcastle-on-Tyne, Secretary of.

O.—Messrs. Oppenheimer, Son, and Co., Lond.

P.—Messrs. Peacock and Hadley, Lond.; Mr. F. T. Pain, Lond.; Mr. J. E. H. Parsons, Shipton-under-Wychwood; Dr. S. Parmanandas, Bombay; Messrs. George Philip and Son, Lond.; Dr. Padbury, Axminster; Dr. W. L. Pethybridge, Plymouth; Mr. V. S. Partridge, Lond.; Mr. A. D. Pithie, Lymington; Mr. Charles A. Parker, Lond.

R.—Dr. Henry Robinson, Lond.; Dr. F. J. Rosenbach, Göttingen; Dr. R. R. Rentoul, Liverpool; Royal Dental Hospital of London; Royal Institution of Great Britain, Lond.; Mr. P. C. Ray, Kashinathpur; Messrs. Reitmeyer and Co., Lond.; Royal Academy of Medicine in Ireland, Dublin; Royal Sanitary Institute, Lond., Secretary of.

S.—Dr. J. Saffley, Annan; Messrs. Siemens Bros. and Co., Lond.; Messrs. Spiers and Pond, Lond.; Messrs. Short and Mason, Lond.; Sirdar Rubber Co., Lond.; Professor W. Stirling, Manchester; Mr. R. Atkinson Stoney, Dublin; Messrs. J. Smith and Co., Lond.; S. S. M. W.; Southend Corporation, Medical Officer of Health to the; Sunderland Royal Infirmary, Secretary of; Dr. H. Sinigar, Southall; Messrs. Squire and Sons, Lond.; Dr. Charles F. Seville, Leeds; Mr. P. W. Squire, Lond.; Mr. B. C. Sinha, Naugachia.

T.—Mr. George Thorpe, Eldon Lane; Mr. L. L. Thain, Ewyas Harold; Mr. G. Lestock Thornton, Exmouth; Messrs. Tidman and Son, Lond.; Dr. W. W. H. Tate, Lond.; Mr. E. D. Telford, Manchester.

U.—University of Liverpool, Registrar of; Messrs. Urban and Schwarzenberg, Lond.

V.—Dr. J. E. Viney, Chertsey; Mr. H. Vignoles, Banchory.

W.—Mr. R. N. Weekes, Modbury; Dr. S. A. K. Wilson, Lond.; Dr. Claude L. Wheeler, New York; Mr. W. J. Clarkson Webb, Brighton, Mr. Harold W. Wilson, Lond.; Messrs. Wills, Lond.; West London Post-Graduate College, Secretary of; West Kent General Hospital, Maidstone, Secretary of; Messrs. F. Williams and Co., Lond.; Messrs. Williams and Humbert, Lond.

Z.—Messrs. A. and M. Zimmermann, Lond.

Letters, each with enclosure, are also acknowledged from—

A.—Mr. J. V. Arkle, Kalgoorlie; Mr. G. R. Adam, West Malling; Mr. W. Appleyard, Bradford; Aymard Patent Milk Sterilizer Co., Ipswich; Dr. T. Arnold, Ahoghill; Dr. Adamson, Leeds; Dr. J. Aikman, Guernsey; Dr. F. H. Alexander, Littlehampton.

B.—Dr. H. P. Berry, Grantham; Messrs. K. and J. Beck, Lond.; Miss Breeze, Tangier; Mr. M. M. Bolan, Lond.; Mr. H. Butterfield, Northampton; Belfast District Lunatic Asylum, Secretary of; Dr. A. H. Boon, Chicago; Mr. A. R. Burton, Birmingham; Mr. H. J. F. Bourne, Redhill; Messrs. Boots, Nottingham; Birkenhead Borough Hospital, Treasurer to the; Mr. T. B. Browne, Lond.; Messrs. Brady and Martin, Newcastle-on-Tyne; Mr. E. Blakeney, Roscommon; British Union for Abolition of Vivisection, Lond., Secretary of.

C.—Mr. L. V. Cargill, Lond.; Dr. E. M. Clarke, St. Austell; Dr. M. Connon, Montrose; Dr. P. J. Cammidge, Lond.; Dr. C. Coles, Oxford; C. H. W.; Messrs. E. Cook and Co., Lond.; Dr. A. E. Carver, Torquay; Dr. C. T. T. Comber, Lond.; Mr. F. J. Cruise, Baltinglass; Calcutta Medical School, Secretary of; Mr. A. H. Cheatle, Lond.; Dr. J. A. Clarke, Dunoon; Dr. L. V. Cooper, Rochester; Cunard Steamship Co., Liverpool; Dr. G. Caley, Lond.

D.—Dr. I. F. De Villiers, Vrede; Mr. J. Dunlop, Lond.; Dr. W. Duff, Wishaw; Messrs. A. De St. Dalmas and Co., Leicester; Dr. W. Dunn, Uppingham; Doncaster Royal Infirmary, Hon. Secretary of; Mr. W. H. Duncan, Lond.; Dr. T. Dobson, Windermere; Dr. R. Downer, Woking; Mr. T. Dixon, Lond; Mr. D. Davies, Llangeitho.

E.—Mr. E. P. Edwards, Bodedern; Messrs. Elliott, Son, and Boyton, Lond.; Exmouth Medical Library, Hon. Secretary of; Sir Frederick Eve, Lond.; Messrs. Evans, Sons, Lescher, and Webb, Lond.; Sir P. Eade, Norwich; Mr. W. Edmund, Lond.; Dr. A. Eastwood, Lond.

F.—Mr. J. W. Fox, Southampton; Dr. G. FitzGerald, Queenstown; Dr. F. E. Fremantle, Lond.; Dr. E. G. Fearnsides, Lond.; Mr. W. Foreman, Liverpool.

G.—Mr. D. M. Greig, Dundee; Dr. S. Gill, Formby; Messrs. Grimwade, Ridley and Co., Lond.; Mr. H. J. Glaisher, Lond.; Dr. J. H. Glenn, Dublin; Dr. J. Gardner, Burscough Bridge; Mr. H. Gilford, Reading; Messrs. R. W. Greeff, and Co., Lond.

H.—Mr. W. Handcock, Bradford; Sir F. Hewitt, Lond.; Captain H. S. Hutchison, I.M.S., Bombay; Dr. F. H. Humphris, Lond.; Dr. A. Haig, Lond.; Mr. G. S. Hatton, Stoke-on-Trent; Fleet-Surgeon W. E. Home, R.N., Greenwich; Mr. F. A. Hepworth, Rotherham; Mrs. M. E. Hall, Barnett; Dr. T. Houston, Belfast.

J.—Mr. W. Johnson, Northallerton; J. G. L.; J. A. N.; Mr. T. Jago, Lond.

K.—Dr. W. Knight, Pinetown, S.A.; Professor E. Klein, Chislehurst; Colonel W. G. King, I.M.S., Hatch End; Dr. S. J. J. Kirby, Lowestoft; Messrs. Knoll and Co., Lond.

L.—Mr. T. G. Laslett, Bolton; Messrs. W. Le Lacheur and Son, Lond.; Dr. R. A. Lipter, Winchester; Mr. P. C. Laws, Newcastle-on-Tyne; Dr. R. Lozano, Zaragoza; London Biblewomen and Nurses' Mission, Secretary of; Dr. P. Livingstone, Rochdale; Mr. E. W. Lewis, Southport.

M.—Dr. J. Morley, Manchester; Mr. S. G. Macdonald, Lond.; Dr. G. W. F. Macnaughton, Lond.; Mullingar District Asylum, Secretary of; Dr. C. G. May, Lond.; Mental Nurses' Co-operation, Lond., Secretary of; Mr. A. F. Messiter, Gainsborough; Mr. R. Morison, Newcastle-on-Tyne; Messrs. Mawick, Mitchell, and Co., Paris; Messrs. Macmillan and Co., Lond.; Dr. Mitulescu, Bucharest; Mr. H. T. Mary, Lond.; Mr. W. Mackie, Helensburgh; Medical Correspondence College, Lond., Secretary of; Dr. T. S. Macaulay, Seremban; Mr. J. D. Mortimer, Lond.; Manchester Guardians, Clerk to the; Dr. R. Mackinlay, Newton Mearns.

N.—Mr. W. J. W. Nicol, Lond.; Mr. W. S. Neave, Bournemouth; North Riding Infirmary, Middlesbrough; Secretary of; Mr. L. Noon, Frimley; Newcastle-on-Tyne Hospital for Sick Children, Secretary of; Newport and Monmouthshire Hospital, Secretary of.

O.—Dr. A. W. Oxford, Lond.; Mr. T. T. O'Farrell, Dublin; Mr. W. Oulton, Liverpool.

P.—Dr. J. Paterson, Glasgow; Prestwich Union, Manchester; Mr. H. Perkins, Lond.; Perth Royal Infirmary, Treasurer to the; Dr. H. Playfair, Lond.; Mr. F. H. Preston, Lond.; Miss M. E. Parkington, Eastbourne; Sir G. H. Philipson, Newcastle-on-Tyne; Mr. S. Pringle, Dublin; Dr. E. E. Prest, New Cumnock; Dr. R. W. C. Pierce, Guildford; Pall Mall Press Agency, Lond.; Mr. F. N. Pedley, Lond.; Mr. F. C. Pain, Lond.

Q.—Messrs. Quibell Bros., Newark.

R.—Mr. D. Ranken, Newcastle-on-Tyne; Royal Portsmouth Hospital, Secretary of; R. E. M.; Messrs. Roborat Co., Lond.; Royal Berkshire Hospital, Reading; Mr. C. Richards, Cairo; Dr. J. W. Russell, Birmingham; Dr. A. H. Richardson, Cambridge; Messrs. E. J. Reid and Co., Lond.; Dr. C. Rolleston, Sevenoaks; Dr. R. B. Roy, Gorakhpore, India; Lieutenant-Colonel R. B. Roe, Karachi; Messrs. J. Richardson and Co., Leicester; Dr. J. Rae, Lond.; Royal College of Surgeons, Lond., Secretary of.

S.—Mr. R. Sladen, Lond.; Messrs. W. H. Smith and Son, York; Mr. A. J. L. Speechly, Hutti; Mr. C. Scholl, Liverpool; Mr. A. H. H. Sinclair, Edinburgh; Sanitary Wood Wool Co., Lond., Secretary of; Mr. Morton Smale, Lond.; Dr. T. H. Suffern, Lond.; Rev. J. Standish, Scarrington; Dr. W. W. Stainthorpe, Saltburn; Mr. C. Stonham, Lond.; Dr. E. B. Sherlock, King's Langley; Mr. A. B. Scott, Bournemouth; Mr. A. Stenhouse, Glasgow; Dr. A. Saunders, Lond.; Dr. C. P. A. Stranaghan, Stafford; Salford Union, Clerk to the; St. Mary's Hospital, Plaistow, Secretary of; Mr. J. Sherren, Lond.; Mr. A. Sexlehner, Lond.; Sanitas Electrical Co., Lond.; Dr. A. F. Stevens, Seaford; Rev. J. B. Sidgwick, Ashby Parva.

T.—Mr. H. G. Terry, Bath; Mr. J. W. Thompson, Liverpool; Mr. W. Turner, Lond.; Messrs. J. Timpson and Co., Lond.; Mr. J. Lynn Thomas, Cardiff; Dr. W. Bezly Thorne, Lond.; Messrs. Tylor, Bullmore, and Butterworth, Wisbech.

A Lecture

ON

CANCER OF THE RECTUM AND ITS TREATMENT.

Delivered at St. Mark's Hospital for Cancer, Fistula, and Diseases of the Rectum, City-road, London, E.C., on Nov. 2nd, 1911,

BY P. LOCKHART MUMMERY, F.R.C.S. ENG.,

SENIOR ASSISTANT SURGEON TO THE HOSPITAL; SURGEON TO QUEEN'S HOSPITAL FOR CHILDREN, HACKNEY-ROAD, E.

HISTOLOGICAL TYPES.

GENTLEMEN,—Cancer of the rectum may be of two kinds—epithelioma and adeno-carcinoma. Several other varieties are often described, such as medullary, adenoid, scirrhous and colloid carcinoma, but these are only varieties of adeno-carcinoma, and owe their different appearances to the rapidity of their growth and the secondary changes which they undergo; primarily they are all the same.

Epithelioma occurs only at the anal skin margin and has all the usual histological characters of skin cancer. In the later stages it often invades the rectum, but it is always primarily a skin cancer. Adeno-carcinoma starts in the rectal mucosa, and the cells have the typical glandular arrangement of the crypts of Lieberkühn.

Site of the growth.—The commonest position for rectal cancer is at or about the recto-sigmoidal junction, the next commonest situation is the rectal ampulla, and the least common is epithelioma of the anus. Tuttle gives the following figures: Anus, 6 per cent.; intraperitoneal position, 26 per cent.; supraperitoneal position, 67 per cent. We notice that by far the commonest situation is unfortunately the worst from the point of view of treatment—namely, high up in the rectum and involving the peritoneal cavity.

Age.—Cancer of the rectum may occur at almost any age. The youngest case we have had at St. Mark's Hospital was a girl, aged 15 years, while the oldest, I believe, was a man of 83 years. Statistics show that the commonest age is between 40 and 45. But these figures are not trustworthy, as they do not take into account the numbers of population living per 1000 at each age. And personally I believe the commonest age is between 50 and 60.

Sex.—Cancer of the rectum is apparently slightly commoner in men than in women. Most statistics show about 60 per cent. men.

PREDISPOSING CAUSES.

I do not propose to discuss the very vexed question of the etiology, but only to mention some of the conditions which appear to predispose to cancer of the rectum.

Constipation is often stated to be a cause, but that this is an important cause is open to considerable doubt. One must remember that constipation is very common, while cancer is not. Also constipation is much commoner in the female sex, while cancer of the rectum is slightly more common in the male.

Tuttle is strongly of opinion that muco-membranous colitis is a predisposing cause of cancer. While I should certainly admit that the two conditions are not infrequently mistaken for one another, I have no evidence in my own experience that one is a predisposing cause of the other.

SIMPLE GROWTH AS A PREDISPOSING CAUSE.

Personally, I believe by far the most important predisposing cause is a simple growth in the bowel, such as a polypus or simple adenoma. I have so frequently seen cancer originate in innocent adenomata of the rectum that I look upon all simple adenomata or polypi with the gravest suspicion and recommend their immediate and wide removal. Sometimes a simple adenoma will undergo malignant change when it is quite small; while at other times it will reach a considerable size before the change occurs, but sooner or later I believe it always does become converted into a malignant growth, with the exception of cases in very young persons.

Not long ago I saw a patient who for five years had suffered from symptoms pointing to a growth in the bowel—i.e., bleeding and diarrhœa. When I saw him he had an adenoma, which was obviously malignant, and I have no doubt that the original growth was innocent, but had become malignant during the last few months. Simple chronic ulcer of the rectum may also be the starting point of cancer, and should be looked upon as a predisposing cause. I know of certainly three cases in which there did not appear to be any doubt that cancer of the rectum or sigmoid had originated in an old chronic simple ulcer.

MULTIPLE POLYPI.

No list of predisposing causes would be complete without mentioning multiple polypi of the colon. This is a rare disease in which numerous polypi of an innocent nature occur in the large bowel and rectum. So prone are these polypi to become malignant that I have never yet seen a case in an adult where malignant change had not occurred in one or more of the polypi or did not develop soon afterwards. In two cases which I have seen there were several of the polypi in different parts of the large bowel which had become cancerous.

METHODS OF SPREAD OF THE GROWTH.

Cancer of the rectum, like cancer elsewhere, spreads by the lymphatics and by direct extension of the growth into neighbouring tissues. Epithelioma of the anus spreads both out on to the skin round the anus and up into the bowel. In the bowel the extension of the growth up along the lymphatics can in some cases be felt as chains of nodules passing longitudinally up the bowel. On the skin it has the ordinary appearances of a skin cancer. The glands in the groin are early involved, which is, of course, not the case with cancer of the rectum proper, unless the growth has extended out on to the skin.

Cancer of the ampulla is generally first seen as a circular ulcer which spreads radially. When felt in the rectum it feels like a stricture with a thick lower lip; this is due to the fact that as the ulcer spreads its two opposite edges soon meet on the opposite side of the bowel and the thickened lower edges seem to form a sort of lip or funnel. When the bowel is cut open, however, it will almost always be found that the growth is circular and that there is a portion of the bowel-wall not involved. Ultimately, however, the two opposite edges of the ulcer meet and unite, with the result that the growth involves the entire circumference of the bowel. The circular lymphatics in the submucous layer are early involved, and even though the growth may not have extended round the bowel, cancer cells will almost always be found on the opposite side in this layer. The growth also spreads along the lymphatics both up and down the bowel, more usually to a greater extent upwards. In the case of a posterior growth the lymphatics and glands in the meso-rectum and root of the meso-colon are first involved—first the glands against the bowel, and later those in the base of the mesentery and along the blood-vessels. In the case of growths in the anterior wall the lymphatics on the back and fundus of the bladder in the male, or the uterus in the female, may be involved. Growths at the recto-sigmoidal junction spread into the posterior false ligaments of the bladder and into the root of the meso-colon.

Metastasis does not apparently occur early in the case of rectal cancer, and it is surprising for how long a large rectal growth can exist sometimes without metastatic deposits forming. When metastasis does occur it is usually in the liver. Not long ago I saw a patient who for *six* years had had undoubted cancer of the rectum (verified on two occasions by microscopical examination) for which a colotomy had been performed. At the time I saw him he was still in quite good health, and only consulted me with the object of having the colotomy closed; which was, of course, impossible.

SCIRRHOUS CANCER.

There is a rather rare form of rectal cancer sometimes called scirrhous cancer, in which the mucous membrane appears to be very slightly involved, but the growth extends around the bowel in the submucous coat, accompanied by much fibrosis, so that a tight ring stricture is produced with little, if any, ulceration of the mucous membrane.

SYMPTOMS.

Unfortunately cancer of the rectum causes no symptoms of any importance at an early stage. In fact, a cancerous growth in the rectum is not incompatible with perfect health.

I recently saw a patient who told me that he had only just finished a walking tour through the Welsh mountains, during which he had walked 90 miles in five days, and he felt perfectly well, except that he was troubled with a slight diarrhœa. On examination I found a large inoperable carcinoma of the rectal ampulla.

It is important to remember that such text-book symptoms as loss of weight and cachexia only occur in the later stages of the disease and after the growth has existed for many months. The earliest symptoms in my experience are a tendency to looseness of the bowels, a feeling as if the bowel was not completely emptied after an evacuation, and bleeding. Constipation is not, as a rule, an early symptom, except in cancer high up in the bowel or in the large intestine, and even then it is uncommon.

Slight diarrhœa is the most characteristic symptom and usually has the following characteristics. It is spurious—that is to say, the total quantity passed is often less than normal. The patient has frequently to go to stool, but with very little result, often only a little mucus which may be stained with blood. Exercise and meals usually bring on the diarrhœa. The call to stool is usually very urgent and the patient is afraid to go far away from a place to which he can retire if necessary. The diarrhœa varies very considerably, being worse on some days than on others, often amounting to little more than an unusual irregularity of the bowels. The patient very naturally attributes his symptoms to some error of diet and goes to his doctor for a bottle of medicine to help him. If the doctor gives him some astringent medicine the symptoms will usually be much improved, and it is against this danger that I particularly wish to warn you. No matter how slight the symptoms are, the rectum should always be examined before any drugs are given. I know this is sometimes difficult, as the patient may resent an examination, saying that his symptoms are too slight to make a fuss of. Unless, however, medical men will make it a rule to examine the rectum in all suspicious cases, we can do little to improve the results of operation in rectal cancer. At present about two-thirds of the cases we see have already passed the period at which operation is possible. This is much too large a proportion, and can be much reduced if the doctors who first see these cases will make it a rule never to prescribe for a patient with diarrhœa or rectal symptoms without first making an examination. Too often at present when a growth is discovered and found to be inoperable, the patient, with that desire, which is so common to all of us, of wishing to blame someone other than himself for his misfortune, blames his doctor for not having detected his condition earlier. Morning diarrhœa, or in other words an urgent call to stool on first getting out of bed in the morning, is a common early symptom. Another early symptom is the rapid development of piles, the piles in this case being caused by the obstruction to the veins by the growth in the bowel.

Any of these symptoms which I have detailed may, of course, result from a number of conditions besides cancer, but they should always make us suspicious and lead to an examination. Of course, it is not always possible to detect a carcinoma by the introduction of the finger into the rectum, and the use of the sigmoidoscope may be necessary, but in a great many cases the growth can be felt.

Other common symptoms are discomfort or pain in the sacrum, which is not relieved by lying down, and pain in the lower part of the abdomen, especially before or during an action of the bowels. The bleeding varies very much. Sometimes it is altogether absent, while it may be the first symptom noticed. Mucus in the stools almost always occurs to some extent. I have seen several cases where the symptoms which first drew attention to the condition were those of a slight chronic colitis. When a growth is high up in the bowel increasing constipation is often a prominent symptom and may be the first to attract the patient's attention. As the growth increases in size, pain of a dull aching character usually becomes a prominent symptom. The amount of pain varies, however, very much. Growths high up on the posterior wall usually cause more pain than those on the anterior wall, owing to the fact that they soon press upon the sacral nerves as they emerge from the foramina in the sacrum. It is characteristic of the pain that it is either made worse or not relieved by recumbency.

Soon, owing to the fact that the alimentary outlet is partly blocked and there is consequently considerable accumulation in the large bowel, symptoms of toxæmia begin to make their appearance. The patient is a bad colour, has no appetite, is sleeping badly, losing weight, and, in fact, generally out of condition. I believe that these constitutional symptoms, usually attributed to cachexia from the growth, are in most cases due to auto-intoxication from retained fæcal material. In proof of this I would point to the marked improvement, or complete absence of those symptoms, which generally occurs after colotomy.

The rapidity with which bad symptoms come on is dependent, not I believe, so much upon the type or position of the growth as upon the rate of its growth, and especially the amount of obstruction which it causes. Ulceration of the growth also causes a marked increase in the severity of the symptoms.

With the onset of ulceration septic symptoms may supervene. There may be a mild type of septicæmia with occasional rises of temperature, or an abscess may form.

A considerable amount of inflammation often occurs round the growth, giving rise to fixation to other organs, and in the case of anterior growths in male subjects to bladder symptoms. The adhesions so formed to other organs are, however, often not extensions of the growth, but purely inflammatory. This is an important point, as it means that fixation to the bladder, for instance, does not necessarily contra-indicate a good result from removal of the growth. I have several times had cases where adhesions of this nature were broken down during removal of the growth, and no recurrence has followed in the involved organ or organs left behind. The same also applies to glands; many of the enlarged glands in the neighbourhood of a carcinoma are inflammatory only (that is, in cases where ulceration of the growth has already taken place), and the fact that they may have to be left behind will not necessarily involve recurrence. I have known several instances of this, and it has been repeatedly noted by other observers.

DIAGNOSIS.

It is not necessary to say much with regard to diagnosis. The really important thing in this connexion is that the medical man who first sees the case should be sufficiently suspicious of the possible presence of carcinoma to insist upon a proper examination. As regards the differential diagnosis between carcinoma, adenoma, and papilloma of the rectum I do not think this is of much importance. The two latter, though innocent growths, should be freely removed in all cases, as they are undoubtedly pre-cancerous, but the removal need not be so extensive as in the case of cancer.

INDICATION FOR OPERATION.

Next to the initial diagnosis of a growth of some sort in the bowel the most important factor is the question of whether the growth can be properly removed or not. This is often a difficult question, and whenever possible, except in cases where removal is obviously possible, no opinion should be expressed without an examination under an anæsthetic and after the bowels have been emptied. Mere fixation of the growth does not always contra-indicate removal, and some of my best results, as regards recurrence, have been in cases where there was a considerable degree of fixation at the time of operation. Extensive secondary glands, fixation by extension to other important organs, nodules in the liver, and the size or connexions of the growth rendering it mechanically impossible to remove it, are, of course, contra-indications; but the position of the growth alone, as, for instance, that it is very high up, does not necessarily contra-indicate successful removal, and with increasing experience I find that what I often was accustomed to look upon as contra-indications to removal are no longer to be feared.

CONDITION OF PATIENT.

The condition of the patient is a factor which must always be taken very seriously into consideration, and for this reason alone a consultation with the family physician is of the utmost value.

The fact that the patient is young is no contra-indication to removal, though I have sometimes heard it stated that in young people it is useless to remove the growth, as recurrence occurs so rapidly. It is true that if recurrence does occur it will do so rapidly, but if recurrence occurs at all it is evidence that the growth was not adequately removed in the first instance, and as our object should always be to remove the growth widely and completely, this factor has no significance. Young people stand operations well, and the

chances of a cure are therefore greater than in more elderly subjects.

Alcoholic subjects are entirely unsuitable for such a serious operation as rectal excision. Thin and wasted individuals, in spite of their apparent lack of vitality, often do well, but fat patients do very badly, and I am personally more afraid of stout adipose patients for this operation than of any other type. As a rule, their vitality is low, they heal badly, there is poor blood-supply to the cellular tissue, which is in excess, and owing to the presence of fat in the bowel and abdominal wall the operation is rendered very difficult.

Bright's disease and diabetes would certainly contra-indicate operation except in most exceptional circumstances.

PROGNOSIS.

This is a very difficult subject and one about which a reliable opinion is difficult to express. Of late years, however, since it has been the practice to perform operations for rectal cancer, which enable wide removal of the growth and surrounding tissues, far better results have been obtained than was previously the case, and the prospect of complete freedom from recurrence is now considerable if the patient is operated upon before the growth has reached a large size and the bowel is freely resected. The present radical operation for cancer of the bowel is of too recent date for any reliable statistics to be possible. But from my own experience I should estimate the patient's chances of complete freedom from recurrence as quite good in favourable cases, and even where recurrence does occur at least two years more of life is to be expected. Personally, I have had only one case which recurred within two years, and several which have gone well over the three-year limit, while five are over the five-year limit.

TREATMENT.

There is at present only one form of treatment which is in any sense radical or can offer any hope of cure—namely, complete removal of the growth by operation. It is to be hoped that the time is not far off when some better and more effective method of treating cancer will be discovered. I believe that if some of the money now being spent by the Government on social reform were utilised to aid in finding a cure for cancer, it would be of far greater benefit to the race, and would, I believe, soon result in removing or mitigating one of the greatest evils of modern times. Instead of this, however, everything is left to private enterprise, and a discovery which might be hastened by many years by the mere expenditure of sufficient money is left to chance.

The operations for excision of rectal growths have improved in an extraordinary manner in the last ten years, and it is now possible to remove successfully growths which then were considered to be quite beyond operative interference. Herbert Allingham, one of the boldest operators who ever lived, never attempted to remove any growth the upper limits of which he could not reach with his finger. Whereas now we frequently remove growths the lower limits of which can hardly be reached by the finger, and the distance of the growth from the anus is no longer a matter of serious importance.

What in many ways is a still greater improvement is that we are now able by improved technique to obtain in a few cases primary union in the wound and aseptic healing. I have myself now had several cases in which this ideal method of healing has been obtained, and I look forward to the time when it will be the rule instead of the exception to obtain aseptic healing in these cases. The difficulties are many, but since they can be overcome in a few cases, they can be overcome in all, and the improvement in the results will be enormous. To show the importance of this I have only got to mention that at present 90 per cent. of the deaths from excision of the rectum are directly or indirectly due to sepsis. Shock as a cause of death after these operations, serious as they undoubtedly are, can be now completely eliminated as a cause of death, but the dangers of sepsis are undoubtedly very great.

Careful attention to technique in operating, especially in regard to the treatment of the bowel which has to be resected, and care in preserving an adequate blood-supply to the parts left behind, will enable us to prevent sepsis in these cases.

There are, in my opinion, three methods of removing rectal growths which should be used according to the type of case.

Removal by Coccygeal Incision.

1. Local removal of that part of the rectal wall containing the growth through an incision from the base of the coccyx to the posterior edge of the external sphincter, the coccyx being removed, the rectal wall being subsequently sewn up, with both rectal and posterior drainage. This method is the least dangerous of all, being almost free from serious risk, but is only applicable to growths in the ampulla of an innocent nature, such as adenoma and papilloma. It does not give wide enough removal for growths already malignant.

2. The removal of the entire rectum and part of the sigmoid through the same incision, as mentioned in the first method, by a method described by me a few years ago,[1] has given, in my experience, the best results of any in suitable cases, but is not so good as No. 3 in cases of carcinoma at the recto-sigmoidal junction. It has the advantages that it allows of restoration of the bowel, and is a less serious operation than No. 3. Moreover, it can be more quickly performed; it is, however, more difficult.

Abdomino-perineal Excision.

3. Abdomino-perineal excision is the best method for growths at the recto-sigmoidal junction, or which have already reached a large size—i.e., borderland cases. It involves two separate operations, performed, as a rule, consecutively, and there is an inevitable waste of time between the two stages. It enables us to deal with cases previously considered inoperable. It does not necessarily involve a colotomy, and the bowel can in suitable cases be restored. It allows of very extensive removal. It is, however, a very serious operation, and has been attended, even in the hands of expert surgeons, with a very heavy mortality—somewhere not far short of 40 per cent. My own mortality was at first serious with this operation, but I find that with increasing experience I have been able to considerably reduce it, and in the last two years it has been cut down by half, and in time I hope it will be still further reduced. The shortest time in which I have succeeded in doing the complete operation is 85 minutes, and unless one has considerable experience and expert assistance it may easily take two and a half hours.

I do not believe that it is good practice to perform one uniform operation for rectal cancer, nor does it give the patient the best chance. Each case must be judged on its merits, and it is quite unnecessary to condemn all patients to a permanent colotomy. I have two patients who are alive and quite well now, who have both got rectums which function in the normal manner and who had rectal excisions performed—one six and a half and the other seven and a half years ago.

Operation in cases of epithelioma of the anus or in which the anal region is involved.—In all such cases it is imperative that the sphincters should be freely removed together with the skin round the anus. With this object an elliptical incision should be made round the anus and deepened down into the ischio-rectal fossæ. The whole bowel and surrounding tissues must then be cleared away. As it is quite impossible for the patient to have any control subsequently if the bowel is brought down, a permanent colotomy should be established and the perineum entirely closed up.

I do not propose in this lecture to describe the details of these three operations, as space will not allow of this. They are all of them difficult operations, and I should strongly advise anyone wishing to perform them to practise them first on the cadaver before proceeding to operate upon their patients.

PALLIATIVE TREATMENT.

Colotomy.

At one time it was the practice to perform colotomy in nearly all cases and to reserve excision for a very few favourable cases. This led among other things to a reaction against colotomy, and I have seen it asserted recently that this operation is not worth doing except for obstruction, present or threatening. I do not, however, agree with this, and, on the other hand, I am sure that colotomy greatly prolongs life in inoperable cases and adds most materially to the patient's comfort. It very markedly relieves the discharge from the bowel, which causes so much distress, and by enabling the bowel to be kept clean prevents septic complications. I am sure that in most cases it very materially delays the rate of growth of the tumour. I advise colotomy in cases where there is no obstruction for these reasons, and have seen most gratifying results.

[1] Brit. Med. Jour., June 1st, 1907.

Colotomy should be performed early if it is to do good, and not left till the patient is already in serious distress, as, under the latter conditions, it adds to his discomforts, and the beneficial results are not so obvious or, in fact, sufficient to justify its performance. The presence of a colotomy opening, if the operation has been well done, is not incompatible with the patient living an ordinary life and getting about in the usual way.

Curetting.

This is a very useful operation in cases where the growth is quite low down in the bowel. It consists in thoroughly curetting away the growth, or at least all that part of it which protrudes into the bowel, under an anæsthetic. The rectum is plugged for a few hours to control the bleeding, and then kept clean with frequent douches. The curetted area soon heals and for a time the patient is quite relieved of his symptoms. The operation should be repeated when the growth again reaches any size.

This operation gives a surprising amount of relief in suitable cases, and often prolongs the patient's life for a considerable time. I know of one case where a patient was kept alive and in comfort for over five years by this operation. It must not, however, be attempted in the case of growths fixed to the bladder or above the peritoneal reflection.

Other Palliative Methods.

The action of radium is now being largely resorted to in the treatment of inoperative malignant growths, and as the question of its employment will almost certainly arise in those cases in which radical operation is not possible, it is necessary to have some idea in what type of cases it is worth trying. It must first of all be recognised that radium as a means of curing or relieving cancer in the rectum is at present purely experimental. No positive evidence is at hand to prove that it can cure cancer of the bowel—using the word cure even in the very restricted sense in which it is sometimes used in relation to operation. Most of the evidence is entirely opposed to the belief that cancer of the rectum can ever be cured by the action of radium. In a few cases some relief, and in a very few cases considerable improvement, has followed radium applications. In a large number of cases no benefit at all has resulted, and in some cases the symptoms have been rendered worse.

Radium should only be used as an adjunct to operative treatment, never in place of it. It is no use trying radium unless a very large quantity of active radium in suitable applicators is available, and this must be used by experts in its application. My own view is, that unless marked improvement follows one large dose the treatment should be discontinued. It is no use trying it in cases where the growth is not easily within reach of the finger, and applications other than those applied directly to the growth are useless. I have very grave doubts whether, taking into consideration the expense and inconvenience to the patient of the treatment, it is worth trying, or will be likely, even in favourable cases, to give better results than careful attention in the form of antiseptic and astringent douches to the bowel.

As regards other methods of treatment, such as special diets, animal extracts, hot air applications, fulguration, &c., I have never seen anything to justify the belief that any good whatever can come of their use. They cause the patient considerable discomfort and inconvenience, without the smallest possibility of doing good.

APOTHECARIES' HALL OF IRELAND.—The following have been appointed examiners for the ensuing year:—Court A.—Chemistry and Physics: Professor H. Ryan and Mr. J. J. O'Sullivan. Biology and Physiology: Dr. G. M. Keating and Dr. W. O'Kelly. Anatomy: Mr. D. Burke Kennedy and Mr. A. Charles. Pharmacy: Dr. F. G. Adye Curran and Mr. J. D. Crinion. Materia Medica: Mr. T. G. McGrath and Dr. J. C. McWalter. Pathology: Dr. R. J. Rowlette and Dr. G. B. White. Medical Jurisprudence: Mr. F. K. Cahill and Mr. W. Fottrell. Hygiene: Sir C. Cameron and Mr. R. P. McDonnell. Medicine: Dr. J. Lumsden and Mr. C. J. Powell. Surgery: Sir T. Myles and Professor Conway Dwyer. Midwifery: Mr. Seymour Stritch and Dr. P. T. McArdle. Ophthalmology: Dr. E. Magennis and Dr. R. J. Montgomery. Court B.—Chemistry: Dr. J. C. McWalter and Mr. R. P. McDonnell. Materia Medica: Mr. J. D. Crinion and Dr. F. G. Adye Curran. Pharmacy: Mr. J. A. Whelan and Mr. T. G. McGrath.

RADIOGRAPHY IN INTESTINAL STASIS.[1]

BY ALFRED C. JORDAN, M.D. CANTAB.,
MEDICAL RADIOGRAPHER, GUY'S HOSPITAL, AND ROYAL HOSPITAL FOR DISEASES OF THE CHEST.

(With Illustrative Plates.)

INTESTINAL stasis is a chronic disease due to the retention for too long a time of the intestinal contents, and the toxic absorption resulting from this undue retention. The symptoms may be slight or severe, but they are very definite. They may be enumerated as follows: abdominal pain, often severe; general depression and want of energy, which may be so extreme as to make life intolerable; poor appetite, with attacks of nausea or vomiting; a bad taste in the mouth; breath of an unpleasant odour; headache, backache, muscular pains and aching in the joints; cold hands and feet and other signs of a poor circulation. Constipation is usually a marked symptom; often it persists in spite of all treatment, the patient being compelled to rely on purgative drugs and injections. Flatulence is always present and leads to attacks of abdominal distension. There is tenderness to pressure over the abdomen, especially in certain regions, of which the right iliac fossa is the most usual. The skin is stained, sometimes to a deep brown colour; it feels unhealthy, as though wanting in elasticity; the sweat has a disagreeable odour. The breasts show changes such as are usually described as chronic mastitis; in more advanced cases cystic degeneration takes place, and the breasts are then in a condition in which a transition to cancer is very liable to occur. Similar changes are produced in other glands, and at operations on these patients chronic pancreatitis is found to exist; in many cases cholecystitis is present also, and gall-stones are very often found.

There can be few diseases in which the symptoms and signs are more definite or more constant, and yet this condition of intestinal stasis was not recognised or understood until Mr. W. Arbuthnot Lane described it, and it is to his accurate and thoughtful observations that we owe our present knowledge of the causes, symptoms, and treatment of intestinal stasis. Mr. Lane has described the anatomical changes that lead to the disease and the secondary effects that follow.[2] It is in this part of the work that I have been able to bring the resources of radiography to his aid by obtaining upon the fluorescent screen and upon photographic plates actual irrefutable ocular evidence of the reality of the changes under consideration.

All mammalian animals retain fæcal matter in the large bowel and are subject to some amount of intestinal absorption. In the view of Metchnikoff this absorption of toxins causes changes which shorten their lives.

Effects of the Upright Posture.

In the human subject the position of the abdominal viscera is altered fundamentally by his adoption of the upright posture. Man gained enormous advantages thereby, but as usual it carried with it certain disabilities, and one of the greatest of these is due to the effect of gravity, which causes the heavier of the abdominal viscera to fall, and in so doing to pull upon their attachments. This tendency of the viscera to fall is accentuated by civilisation, for the upright posture, whether in standing, sitting, or walking, is maintained all day—i.e., for 17 out of the 24 hours—and is only relaxed when the subject is in bed.

"Visceroptosis."

The heaviest parts of the alimentary canal are the stomach, when full of food, and the large intestine when loaded with fæces, and the tendency of these parts to drop is well known. The name "visceroptosis" is often used to denote the fact that the viscera (or some of them) are dropped; in this sense there is no harm in using the word, though it is a clumsy word, and is not needed. Unfortunately it is often used to designate other conditions supposed to be associated with dropping of the viscera; more particularly to weakness of the muscles of the abdominal wall, with bulging of the lower part of the abdomen. Now I find that in many of the most extreme cases of dropping of the viscera there is

[1] A paper read before the Section of Electro-Therapeutics of the Royal Society of Medicine on Nov. 17th, 1911.
[2] Brit. Med. Jour., April 22nd, 1911.

absolutely no tendency for the abdomen to be prominent in its lower part; the abdomen is perfectly flat when the patient stands. When flatulence is severe there may be some *general* prominence of the abdomen. Hence it is better to refer to the condition as "dropping" of the particular viscera concerned.

Anatomical Changes accompanying Dropping of the Viscera.

To Mr. Lane we are indebted for demonstrating and explaining the mechanism of the changes brought about by the dropping of the viscera.[3] When the viscera begin to drop they exert a drag upon the mesentery; this results in the formation of thickened bands in the mesentery. These bands become so thick and strong in certain cases and in certain parts as to form supplementary mesenteries, which support the bowel and tend to prevent the dropping. These "adhesions" are entirely non-inflammatory in origin; they are brought into being as the direct result of preternatural strain, just as in certain handicrafts abnormal thickenings and spurs of bone arise, and give additional strength to parts which are too weak to stand the unnatural strain put upon them.

Kinks.

If the above-mentioned adhesions were equally strong in all parts the viscera would be held up uniformly and all would be well. Unfortunately they are often strong in some places, weak or absent in others; consequently the bowel is held up by them at certain points, and kinks are produced which lead to some degree of obstruction. In severe cases the obstruction is extreme.

The Duodenum.

There are certain points at which the kinks are specially liable to occur when the bowel drops. Following along the digestive canal from the stomach the first of these is met in the third part of the duodenum, at the commencement of the jejunum. There is normally at this point a peritoneal band fixing the end of the duodenum; this band is apt to become thickened. (Fig. 1A.) In normal cases the jejunum

FIG. 1A

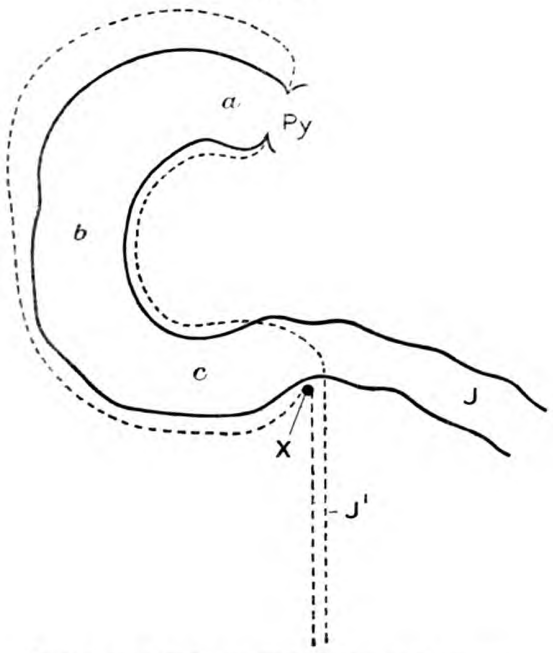

Diagram to illustrate the normal duodenum and jejunum (firm line), and the dilated duodenum and pendulous jejunum (dotted line) due to kinking at the duodeno-jejunal junction by the sharp lower margin of a peritoneal fold, indicated by the point X. The distension of the duodenum is most marked in its first part, where it is least supported, and has a complete peritoneal covering. It is in this part that inflammatory changes are set up in consequence of the abnormal distension. Py, Pylorus. *a*, *b*, *c*, First, second, and third parts of the duodenum. J, J', Jejunum in its normal and in its pendulous position.

[3] Surgery, Gynæcology, and Obstetrics, November, 1910, pp. 496-500.

continues in the line of the duodenum; in the subjects of intestinal stasis, however, the jejunum is frequently dragged down vertically, an abrupt kink being produced. I have described this condition fully elsewhere,[4] but further experience has extended our knowledge of this duodenal kinking, and has shown us that it is scarcely ever the primary abnormality. It is secondary to dropping of other viscera, more particularly of the lower end of the ileum. In healthy persons a bismuth meal passes through the upper parts of the small intestine at a rapid rate; it can be watched running round the coils. At the lower end, however, it encounters the ileo-cæcal valve, and progress here is very much slower; hence the bismuth collects at the lower end of the ileum, in a group of coils normally placed above the pelvis. These coils are very liable to drop into the pelvis. (See Figs. 7, 8, 9, 12, 14, 15, and 16.) The heavy end-coils of the ileum then drag upon the mesentery and exert a downward pull which involves the whole of the small intestine, and causes a downward drag upon the commencement of the jejunum resulting in duodenal obstruction. This is no mere theory or fanciful explanation; I have repeatedly diagnosed the condition beforehand (see Figs. 2 and 4), and subsequently seen it confirmed at operation. I have seen the distended congested duodenum held in a grip at its termination, and the jejunum hanging down vertically at its commencement, and in some cases rotated on its axis, the obstruction being thus increased by torsion of the jejunum.

This duodenal obstruction is not a permanent condition; in slight cases (Fig. 2) it is relieved at once when the patient lies down. It is worst when the patient is compelled to remain upright for long periods, and when he is, for any reason, in an exhausted condition. The mechanical consequences of the kinking are very obvious when they are looked for. The first result is distension (Figs. 3 and 5); this is greatest in the first part of the duodenum—the part which is unsupported and has a complete peritoneal covering. The next result is congestion; later ulceration occurs in the congested mucous membrane. At operations for intestinal stasis, if the duodenum be examined it is nearly always found to show well-defined evidence of congestion; it is full, even distended, thick, red, and prominent. These appearances are seen even in patients who have never had symptoms referable to the duodenum. Very often, however, the symptoms have been severe; there has been great pain, which has often been most persistent, and there has been vomiting. The pain is often severe long before the congestion of the duodenum has gone on to the formation of an ulcer. Pronounced radiographic evidence of duodenal obstruction due to kinking may be obtained in most cases before operation. It is necessary to bear in mind, however, that the kinking is intermittent; it is most severe when the patient is at his worst, as when he has been at prolonged hard work in the upright posture. The obstruction passes off after the patient has been kept in bed for some days, except in severe cases, when it may persist for a week or more. The method of carrying out the examinations was described by me in the paper to which I have already made reference.[5]

The Ileum.

We have now to consider the changes that occur in intestinal stasis at the lower end of the ileum. I have already given an account of these[6]; further experience has fully borne out the results there described, and has enabled me to advance greatly in accuracy of diagnosis. I have now examined a large number of patients, and have subsequently been present at the operation and been able to see the actual condition of the parts, so that, as with the duodenum, there is no room for doubt as to the reality of the anatomical changes first described by Mr. Lane, and now found repeatedly by all surgeons who look for them.

The dropping of the lower coils of the ileum has been described already; it leads to considerable delay in the emptying of the contents of the ileum into the cæcum, especially while the patient's body is erect. A long terminal coil of the ileum rises almost vertically to the ileo-cæcal entrance. (Figs. 7-9, 12, 14-16, 18. This long coil is present in many cases, and leads to a varying amount of delay; in the slight cases it is freely moveable (Figs. 7, 16,

[4] Brit. Med. Jour., May 20th, 1911.
[5] Loc. cit.
[6] Lane's Ileal Kink, Practitioner, April, 1911.

and 18), and pressure upon it with the fingers (while the patient is recumbent) may cause no pain. In other cases there is definite tenderness to pressure at one or more points, the most usual being at the point where it crosses the pelvic brim or at the ileo-cæcal entrance. If there is a fixed point along the terminal coil of the ileum, this point is usually tender also. (Figs. 8, 9, 12, and 15.)

The discovery of a fixed point can be made with great accuracy by means of the fluorescent screen while there is bismuth in the long terminal coil of the ileum; a fixed point here is of the greatest importance, for it indicates the presence, in the particular patient, of a "Lane's ileal kink." The fixity is demonstrable in three ways. Firstly, by observing the movements accompanying deep respiration, when the cæcum is seen to move freely up and down, taking with it the end of the ileum as far as this is free, while the fixed point retains its position unchanged. Secondly, by pressure with the fingers (wearing protective gloves), when the part above and below the fixed point may be moved, but the deepest pressure fails to move the fixed point. Thirdly, by an examination in the upright posture, when the cæcum will fall into (or at any rate toward) the pelvis, leaving the fixed point of the ileum tied up. It is in the upright posture that the effect of an ileal kink is most severe, the two portions of the terminal coil, above and below the kink, hanging down vertically, and producing extreme obstruction in severe cases. (Fig. 15.) Individual cases show great variety in the form of the terminal coil, and the position of the kink. (See Figs. 7–18.) The ileum may be held up at more than one point along the terminal coil (Fig. 12); again, it may be grasped so securely and tightly as to produce permanent obstruction, even in the recumbent posture. (Fig. 12.) The obstruction may be so extreme as to lead to great dilatation of the end of the ileum, which may actually exceed the cæcum and ascending colon in diameter. (Fig. 13.)

The corkscrew formation sometimes shown by the lower portion of the long terminal coil of the ileum is evidence of the manner in which this coil is pulling upon its mesentery. (Fig. 14.)

As a result of the stasis in the ileum bacteria, normally confined to the large intestine, ascend the ileum, giving rise to decomposition of its contents. This is evidenced in the upper parts of the small bowel as pancreatitis and cholecystitis, and the unpleasant breath of these patients bears further testimony to the bacterial invasion of the upper regions of the intestinal tract.

The Appendix.

The appendix is often involved in the newly formed bands that arise in the ileo-cæcal region. It may be held at one point, so that when the patient stands and the cæcum drops the appendix is hitched up at the fixed point and obstructed. Distension of the distal portion of the appendix then occurs and inflammation follows. It is obvious to anyone who approaches the subject without prejudice that the "adhesions" frequently found in the neighbourhood of the appendix cannot be inflammatory in origin; they are often disposed in sheets, and the fingers can then be inserted between the mesentery proper and these adventitious mesenteries. It is certain that the primary disorder is the kinking of the appendix by these newly formed bands; the appendicitis is a consequence of the kinking.

As already stated, the tender spot in the right iliac fossa is usually localised accurately to some point along the end coil of the ileum; it has nothing to do with the appendix. In a good many cases one is able to go further, for a little bismuth is found to have entered the appendix. In such cases direct pressure can be brought to bear (by means of the fingers) upon the appendix, and the absence of tenderness of this organ can thus be confirmed. (Figs. 18 and 20.) Conversely, the discovery of a tender appendix is important, while fixity of the appendix, disclosed in this manner, may also be of consequence.

Ileal Stasis.

I have stated already that considerable delay in the passage of the intestinal contents from the ileum to the cæcum is produced by the falling into the pelvis of the lower coils of the ileum, leaving a long terminal coil rising to the cæcum. The delay thus brought about is independent of kinking, and may be great, especially in the upright posture. The delay is greatest in feeble subjects, and in them, even in the supine posture, there is often the greatest difficulty in the way of the passage of the contents from the ileum to the cæcum; they are unable to surmount the obstacle formed by the promontory of the sacrum and the pelvic brim. (Figs. 10 and 11.)

The Hepatic Flexure.

The next part of the intestine at which obstruction by bands is liable to occur is in the region of the hepatic flexure, and just beyond, in the first part of the transverse colon, where bands sometimes arise, running from the under surface of the liver down to the transverse colon. This is much less common than in the cæcal region, but when bands occur at the commencement of the transverse colon they may produce great obstruction. The contents of this part of the bowel are solid; hence the effect of a slight diminution of the calibre of the gut is far greater than in the case of the

DESCRIPTION OF ILLUSTRATIONS.

(Confirmed by operation.) The duodenum appeared to be writhing. *a*, *b*, *c*, First, second, and third parts of the duodenum. Cr, Crest of ilium. U, Umbilicus.

Fig. 4.—Stomach and duodenum, taken seven hours after a bismuth meal, showing an early stage of kinking at the duodeno-jejunal junction. Note the jejunum passing vertically downward at its commencement. At the time of taking this skiagram a quantity of bismuth had passed through to the hepatic flexure. The delay in the stomach and duodenum is due solely to the duodeno-jejunal kinking. *a*, *b*, *c*, First, second, and third parts of the duodenum. Jej, Jejunum. Py, Pylorus. H F, Hepatic flexure. U, Umbilicus.

Fig. 5.—Duodenum showing well-marked kinking at the duodeno-jejunal junction. The duodenum is distended. It was seen to be contracting actively against the obstruction produced by the kink. *a*, *b*, *c*, First, second, and third parts of the duodenum. Py, Pylorus.

Fig. 6.—Horseshoe loops of ileum. Taken ten hours after a bismuth meal. The loops were slightly fixed at two points. (Loose adhesions were found at the subsequent operation.) U, Umbilicus.

Fig. 7.—Taken seven hours after a bismuth meal, showing a long terminal coil of the ileum, free from tenderness or obstruction. U, Umbilicus.

Fig. 8.—Ileal kink. Taken 25 hours after a bismuth meal, showing a long, terminal coil of the ileum rising out of the pelvis; fixed by adhesions at the point X, close to the ileo-cæcal entrance. There was tenderness to pressure at this point. The dropped transverse colon is also shown. U, Umbilicus (confirmed by operation).

Fig. 9.—Ileal kink. Taken 10½ hours after a bismuth meal, showing the long terminal coil of the ileum rising out of the pelvis. Fixed by adhesions at the point X. In the same subject as Fig. 17. (Confirmed by operation.) U, Umbilicus.

Fig. 10.—Ileal stasis—in a girl aged 13. Taken 10 hours after a bismuth meal. (In the same subject as Figs. 20 and 23.) U, Umbilicus.

Fig. 11.—Ileal stasis, in a woman aged 40. Taken 37 hours after a bismuth meal. After 85 hours there was still some bismuth in the end of the ileum. Very severe symptoms (as described on p. 1828) cured by the operation of "short-circuiting." U, Umbilicus.

Fig. 12.—Ileal kink, in a man aged 71. Taken 24 hours after a bismuth meal. Showing a long terminal coil of the ileum, hitched up for the upper 3 inches and obstructed in the last inch. (Confirmed by operation and the patient cured.) U, Umbilicus.

Fig. 13.—Taken 24 hours after a bismuth meal, showing extreme obstruction by adhesions at the end of the ileum, with enormous dilatation of the ileum, in a man aged 26. Cured by division of the adhesions. U, Umbilicus.

Fig. 14.—Taken 5 hours after a bismuth meal, in a man of 32, showing a long terminal coil of the ileum, hitched up near the ileo-cæcal valve, and a corkscrew formation in its pelvic portion, showing that the coil was pulling upon its mesentery. Three hours later this long coil still contained bismuth. U, Umbilicus.

Fig. 15.—Ileal kink, in a man aged 36. A sharp kink, causing obstruction, is shown at a point 4 inches from the ileo-cæcal valve. At this point the ileum was firmly fixed to the iliac fossa. Above and below this point the gut was freely moveable. (Confirmed by operation.) U, Umbilicus.

Fig. 16.—Taken 10½ hours after a bismuth meal, in a woman aged 51. The long terminal coil of the ileum is pulling upon its mesentery, but is not fixed or kinked.

Fig. 17.—Taken 47 hours after a bismuth meal, in the same subject as Fig. 9 (aged 57). Fibrous bands ran from the under surface of the liver down to the transverse colon, obstructing it just beyond the hepatic flexure. (Confirmed by operation.) U, Umbilicus.

Fig. 18.—Taken 5 hours after a bismuth meal, in a man aged 49. The terminal coil of the ileum is unobstructed. The appendix is well shown by the bismuth it contains. No tenderness of the ileum or the appendix.

Fig. 19.—Taken 102 hours after a bismuth meal, in a man aged 36, showing extreme stasis in the transverse colon, which is greatly elongated and dropped. The hepatic flexure does not rise as high as the iliac crest. Trans, Transverse colon. Rect, Rectum. U, Umbilicus.

Fig. 20.—Taken 34 hours after a bismuth meal, in a girl aged 13 (the same subject as Figs. 10 and 23), showing marked dropping of the transverse colon. The appendix is also shown.

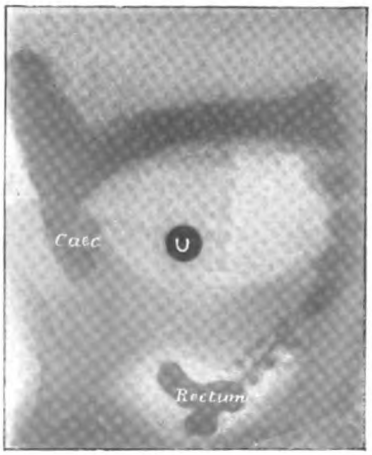

FIG. 22.

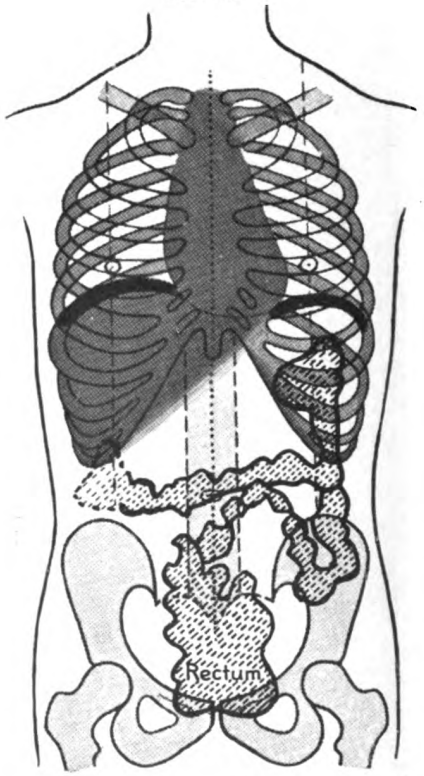

FIG. 23.

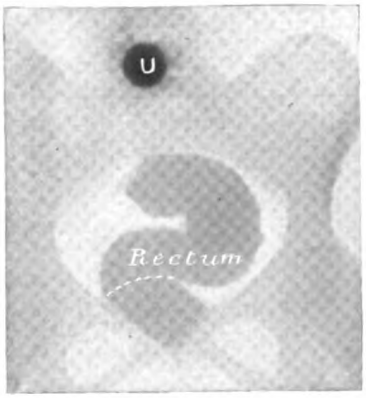

FIG. 25.

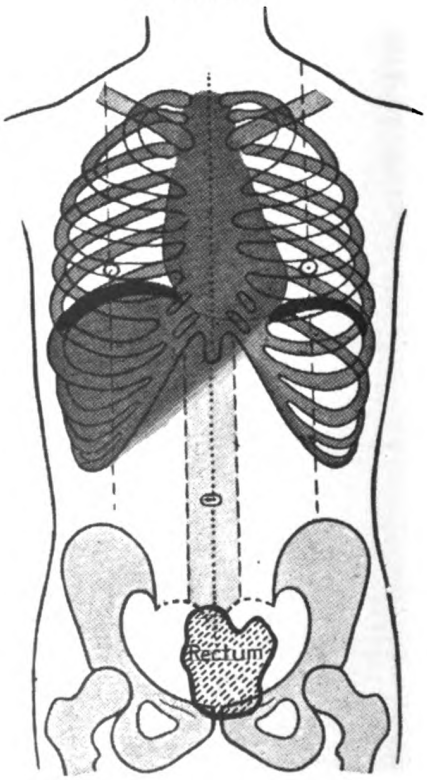

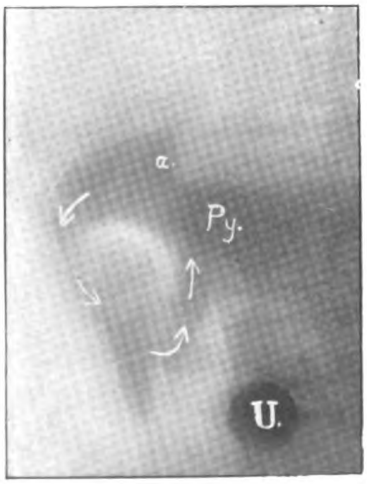

FIG. 24.

To illustrate Dr. Alfred C. Jordan's Paper on "Radiography in Intestinal Stasis."

Fig. 21.—Taken 20 hours after a bismuth meal, in a man aged 54, showing the short, straight sigmoid tied down, and its lumen narrowed by adhesions, and numerous diverticula communicating with the central lumen. (Confirmed by operation and the patient cured.) U, Umbilicus.

Fig. 22.—Taken 80 hours after a bismuth meal, in a woman of 46, showing marked stasis in the large bowel, and a greatly elongated sigmoid and rectum. There was also stasis, exceeding 40 hours in duration, in the end of the ileum, much as in Fig. 14. A remarkable cure was achieved by the operation of "short-circuiting."

Fig. 23.—Elongated and dilated S-looped rectum, in a girl of 13 (same subject as Figs 10 and 20), taken 58 hours after a bismuth meal. There was an evacuation every day or two, but only a small portion of the rectal contents was eliminated at a time. The portion marked off by a dotted line represents a good-sized motion.

Fig. 24.—Skiagram of a "vicious circle" following gastro-jejunostomy, showing the course taken by a bismuth meal from the pylorus through the duodenum, and back again into the stomach by way of the gastro-jejunostomy opening. The operation had been performed eight months previously for the cure of a duodenal ulcer, but the patient, after a brief period of relief, had so much pain and vomiting and bile, that the surgeon (after the X ray diagnosis) reopened the abdomen, and closed up the gastro-jejunostomy opening. (See p. 1827.) a, First part of the duodenum. U, Umbilicus. Py, Pylorus.

Fig. 25.—Taken nine hours after a bismuth meal in a case of severe intestinal stasis, cured by the operation of "short-circuiting." The whole of the bismuth is in the rectum, proving that all intestinal stasis has been abolished.

small intestine. (Fig. 17.) If torsion of the bowel behind the fixed part occur, the condition known as "volvulus" will be brought about.

The Splenic Flexure.

The splenic flexure is normally fixed below the diaphragm by the costo-colic ligament; this is always a strong band, and it keeps the splenic flexure in place even when the ascending and transverse colon are dropped so that the hepatic flexure does not rise above the iliac crest, while the transverse colon hangs in a great loop, the middle of which occupies the pelvis in company with the dropped cæcum, the dropped great curvature of the stomach, the dropped lower coils of the ileum, the sigmoid flexure, and the rectum, all pressing upon the pelvic organs proper. (Fig. 19.) In such a case there is a very long rise from the lowest part of the transverse colon to the splenic flexure, and, especially in the upright posture, fæces may be retained for days in the transverse colon.

The Sigmoid Loop.

The sigmoid loop is very frequently the seat of abnormal bands or adhesions in the peritoneum; they pass down to the outer surface of the meso-sigmoid. In some cases they bind down the whole of the sigmoid, which then takes a short, straight course from the iliac crest obliquely downward and inward to the rectum. This state of affairs is favourable to the patient unless the tube be actually narrowed by pressure of the peritoneal bands upon it; narrowing in this region causes obstruction, and diverticula may be produced, communicating with the narrowed central lumen of the sigmoid. (Fig. 21.) In other cases only the ends of the sigmoid loop are fixed by bands, close together, the loop itself being free, and projecting into the false pelvis. Thus two kinks are produced, the lower of which is a very sharp one and may cause great obstruction. This obstruction leads to lengthening of the loop, and renders it very liable to the occurrence of volvulus. The most severe case of volvulus I ever saw was found at operation to be produced in this way. In other cases the upper part only of the sigmoid loop is fixed down; the lower part then runs without separation into the rectum, forming a long mobile tube in the pelvis. (Fig. 22)

The Rectum.

An elongated S-looped rectum is not uncommon in the subjects of intestinal stasis, more especially in children (Fig. 23), and it is clear that in efforts to defæcate the pressure brought to bear upon the abdomen by the abdominal muscles and diaphragm is in the long axis of the body, and is hence at right angles to the length of the loops of the rectum. The effect of such efforts is to press the loops closer together, and increase the lateral elongation. Thus the condition becomes steadily worse; an enormously capacious rectum is produced, and is continuously packed with fæces. There may be a full-sized motion daily, but only a small portion of the rectum at the lower end is evacuated thereby, leaving by far the greater part of the fæces to stagnate and to poison the system (see Fig. 23). The results of this poisoning are very serious, especially in children, whose vitality and resistance to micro-organisms are thus lowered so that they are rendered very liable to tuberculous disease. It is a suggestive fact that children suffering from tuberculous disease of the bones or joints are always found to have an elongated rectum. This is yet another fact which I have often been able to ascertain by the X rays in the first case, and subsequently seen confirmed by operation.

Treatment.

We have seen that the anatomical changes found in intestinal stasis affect every part of the intestinal tract, and that in most cases several parts are affected, though to a varying extent. Obviously the treatment will depend on the degree of affection of the various parts in the individual case.

To take an example. A patient may have symptoms pointing to the presence of a duodenal ulcer. The X ray examination may provide indisputable evidence of the presence of duodenal kinking (and I have found such evidence very often in patients with symptoms pointing to duodenal ulcer—e.g., Figs. 1, 3, 4, and 5). So far the clinical diagnosis has been confirmed, for duodenal kinking, as already explained, is very likely to lead to a duodenal ulcer. We must not rest here, however; we must follow the bismuth meal further, and we shall find in every case some degree of kinking or obstruction at the lower end of the ileum. We may find very definite obstruction in this region; it becomes clear at once, therefore, that the mere treatment (whether medical or surgical) of the duodenal affection would not be a rational procedure. In following the bismuth meal still further through the large intestine we are likely to find further evidence of stasis, possibly of very severe stasis. Hence, it is clear that we are never wise in applying treatment for the cure of duodenal ulcer until we have investigated the entire alimentary canal. As a matter of fact, the duodenum is the only portion of the alimentary canal that is never affected singly.

Gastro-jejunostomy.

Hence the operation of gastro-jejunostomy for the cure of duodenal ulcer is not rational; this operation should be reserved for cases of actual organic stenosis of the pylorus or duodenum. I have now seen a large number of patients at various periods after having gastro-jejunostomy performed for the cure of duodenal ulcer. No doubt many patients have obtained great relief from the operation, but it must be remembered that duodenal ulcer is a very readily curable condition, three weeks' rest in bed sufficing, as a rule, to effect a cure. Thus the recumbency necessitated by the operation would be expected to permit of the cure of the duodenal ulcer, even though no new opening had been made from the stomach into the jejunum. It is true that duodenal ulceration is very apt to recur when the patient returns to his ordinary occupations, and this is frequently the reason for which patients consent to an operation. In the cases, few in number, in which the duodenum is the most serious point of obstruction, the result of gastro-jejunostomy may be permanently satisfactory, although the patients are for ever deprived of a great part of their gastric digestion. The fact should be borne in mind that the operation of gastro-jejunostomy would be expected to do good by holding up the jejunum in such a position as to prevent the occurrence of kinking at the duodeno-jejunal junction for ever after. This good effect is procured quite independently of the making of a new opening between the stomach and the jejunum; it is a benefit bestowed by accident.

In a great many cases, however, the relief obtained by gastro-jejunostomy is merely temporary, not much greater, in fact, than would be obtained by simple rest in bed on a milk diet. I have now examined a considerable number of patients in whom the operation of gastro-jejunostomy had been skilfully performed by eminent surgeons, but intestinal troubles still existed, or had returned after apparent cure. The symptoms complained of are varied: all have pain; many have vomiting, and the vomit usually contains bile and is very distressing; most exhibit all the signs and symptoms of intestinal stasis. An X ray examination in such cases shows various conditions. In most the bismuth meal finds its way out through the new opening at a rapid rate, so that nearly the whole of it has left the stomach within half an hour, provided the patient remain upright.

"Vicious Circle."

In a certain number of cases a "vicious circle" is produced, the bismuth leaving the stomach by the pylorus and returning once more by the new opening, carrying with it

a large quantity of bile. This is vomited, with great pain and distress to the patient. (Fig. 24.) With a view to avoid the possible creation of a vicious circle some surgeons now actually close the pyloric aperture by a process of invagination at the time of performing the gastro-jejunostomy. In other words, they first create a pyloric stenosis and then proceed to cure it by a gastro-jejunostomy. Observing these cases subsequently by the fluorescent screen after a bismuth meal, I have found that while some of the meal passes out by the new opening, a portion is carried on by the powerful peristaltic contractions of the stomach beyond the new opening, and is seen to beat against the pylorus, which has become bulbous in form from the pressure of the gastric contents. The reason these patients are sent for an X ray examination is pain, and there is no possible doubt but that the pain is due to pressure upon the closed pylorus.

The conclusion—the only rational one that can be formed—is that the operation of gastro-jejunostomy should only be performed for the treatment of actual gastric or duodenal stenosis, but not for duodenal ulcer unless in the rare cases in which a series of X ray examinations, properly carried out, has demonstrated the absence of any marked kinking or stasis in the lower parts of the intestinal tract. Now these are the very cases in which duodenal ulcer yields readily to simple medical means with rest in bed, and ordinary precautions suffice to prevent a relapse.

Radical Cure of Intestinal Stasis.

In the more usual case in which the presence of an ileal kink can be demonstrated, the operation of gastro-jejunostomy can do no lasting good; and the same is true of the cases in which there is well-marked stasis in some or all parts of the large intestine. In these cases, surgical treatment, to be rational, must be directed to the cure of the intestinal stasis. This is accomplished by the operation of "short-circuiting," which consists in dividing the ileum near its lower end, and making an anastomosis between this divided end and the upper part of the rectum. By this means the whole of the stasis due to the ileal kink and the large bowel is abolished. The operation, if skilfully performed, is no more risky than other abdominal operations (such as posterior gastro-jejunostomy). The enforced recumbency is sufficiently prolonged to enable the duodenal ulceration to heal, and when the patient resumes his ordinary life there is no longer any drag upon the jejunum leading to kinking at the duodeno-jejunal junction. I have seen patients in whom the symptoms of duodenal trouble were very well marked make a complete and lasting recovery as the result of the operation of making an anastomosis between the ileum and the rectum. The duodenum was not touched at the operation, but it was carefully examined and found to be distended and congested. In one case there was a well-marked duodenal ulcer.

The operation of making an anastomosis between the ileum (near its lower end) and the rectum is the best procedure in all severe cases of intestinal stasis which fail to yield to less radical treatment. The operation has been carefully described,[7] and I need only draw attention to a few points. Where definite kinks are found, due to fibrous bands, the surgeon is often tempted to content himself with their mere division (this was done in Figs. 12 and 13). Experience shows, however, that this is rarely sufficient; the adhesions are apt to reform, and the symptoms return. In making the anastomosis the end of the divided ileum is sutured into the side of the rectum. It is important to make the anastomosis as near the end of the rectum as practicable—at any rate, below the last of the sigmoid kinks described above. If the new opening were made above the sigmoid kink there would be obstruction, and a cure would not be effected. Frequently the temptation is great to clamp the prominent loop of the sigmoid which presents itself in the left iliac fossa (Fig. 22), and to suture the ileum into it; this should not be done on any account. With the anastomosis properly made into the rectum the sigmoid kink, when present, is of great use in preventing the possibility of the ileal contents flowing back into the descending colon, and giving rise to flatulent distension.

After-results.

The results of the operation on the intestinal stasis are very striking. All abdominal pain is abolished; the constipation is relieved; the headache and other aches leave off; a good appetite replaces the nausea; from a state of depression the patients become bright and cheerful; the staining of the skin clears up; the breasts return to their healthy state. A woman, aged 46 years, was recently admitted to Guy's Hospital to have both breasts removed for supposed cancer; there was extreme cystic disease of the sort which commonly becomes cancerous. The X ray examinations revealed the existence of severe intestinal stasis. (Figs. 11 and 22.) Within a week after the intestinal operation the breasts began to improve, and by the end of three weeks they were practically normal; the woman was greatly improved in all other respects; she had begun to gain in weight. This gain in weight occurs in all cases; the circulation improves so that the extremities are found to be warm, and the patients begin to enjoy life again. During the X ray examinations that precede the operation patients frequently tell me they have lost all desire to live, so extreme is the depression produced by intestinal stasis. A careful study of a number of these patients before and after operation has been published by Mr. Harold Chapple.[8] After recovery from the operation a bismuth meal passes through, and is all collected in the rectum by the end of seven or eight hours, proving that all intestinal statis has been abolished. (Fig. 25.)

I trust I have succeeded in showing that intestinal stasis is a most important disease in the diagnosis of which radiography is of the greatest assistance by affording evidence which is positive and beyond dispute of the existence and the position of the obstructions in the intestines which form the subject of this paper. The condition can now be accurately diagnosed beforehand by radiography, and the accuracy of the diagnosis afterwards tested by operation. Obviously this means of diagnosis is of the greatest value.

A CASE OF RUPTURED EXTRA-UTERINE PREGNANCY, WITH REMARKS UPON DIAGNOSIS.

BY ISLAY B. MUIRHEAD, M.D. GLASG.

THE following case of rupture in extra-uterine pregnancy illustrates the uncertainties which surround the diagnosis of that condition. It shows, with reference to several of its supposed necessary accompaniments, that rupture may in some instances run its course without any one of them being observed from first to last. It enables us to realise how serious are the dangers to which the divergence between the clinical facts and the authorised theory may give rise.

The patient, aged 27 years, had menstruated regularly at intervals of three weeks until her marriage some ten months ago. Since then the duration of the "periods" had gradually lengthened, with the result that when seen by me on Nov. 1st last she had been "unwell" for three weeks continuously. There was no pain, and examination at that date seemed to indicate a healthy condition of the uterus and appendages. She was told to rest, and that if the menorrhagia continued curetting would be advisable. On the 5th severe pain was felt suddenly along the right tube, and she became pale, faint, and almost pulseless. Apart from some percussion dulness over the seat of pain the result of the physical examination was still negative. Rupture of an extra-uterine pregnancy was diagnosed and laparotomy advised, whereupon the friends requested that specialist A should be called to consult.

When seen by A on the 6th, 20 hours from the seizure, the pain had much abated and the pulse and colour were not very markedly abnormal. Being unable to discover any lump or undue resistance in the abdomen or vagina, A thought that extra-uterine pregnancy might be excluded, and that the pain was perhaps connected with trouble in the appendix. For the present he advised rest, to be followed in a day or two by curetting. The rest treatment was continued, with temperatures of from 98° to 101° F. till the 9th, when the curetting was done. The uterus was found to be slightly enlarged, but otherwise it was normal. Following the operation the menorrhagia ceased and the temperatures fell to from ½ to 1 degree below normal. On getting up for the first time on the 27th much pain was felt over the abdomen, with the centre now in the left tube and ovary.

On Nov. 29th the patient was seen by consultant B, who,

finding nothing abnormal in the physical condition, was of opinion, notwithstanding the change in the position of the pain-centre, that the symptoms were connected with a "grumbling appendix." Under rest and anodynes the pain diminished, but at 12.30 A.M. on Dec. 2nd it returned in great severity with marked blanching and, now for the first time, some slight tendency to flatulent distension of the bowels.

At 10.15 on the same morning the patient was seen by consultant C, who, perhaps because he was longer-fingered than the others, was able to feel per vaginam some small object, partly firm, partly yielding in Douglas's pouch. C, while more impressed than the others had been by the character and mode of occurrence of the symptoms, was obviously puzzled, and did not seem inclined to interfere with the temporising methods hitherto pursued. I therefore felt obliged to say plainly that in my opinion further delay would place the patient's life in imminent danger, and this, combined with the above discovery of the body in Douglas's pouch, at length overcame C's hesitation.

What was found was briefly this. The pelvis and general peritoneum contained much blood, mostly fluid, but with many soft coagula. There were no firm or encysted blood-clots and no effused lymph, pus, or other definite signs of peritoneal inflammation. Attached to the left ovary was a small-apple-sized cyst containing clear fluid, and in the right tube an inch and a half from the fimbriated end, was a walnut-sized, firm, smoothly oval mass, the source of the trouble. There were no signs of external rupture, and it seems probable that hæmorrhage had occurred inside the tube at the two extemities of the oval, accounting for both the vaginal and the intraperitoneal bleeding. These conditions were dealt with in the usual way, and the patient is now making an excellent recovery.

Reviewing the history, it is evident that the point upon which the diagnosis broke down was the question as to what does or does not constitute evidence of intraperitoneal hæmorrhage. In this connexion it may be observed that the discovery of a small, firm, moveable body in Douglas's pouch, so far from being evidence of blood clots, either fresh or encysted, would seem rather to suggest a fibroid growing by a pedicle from the back of the uterus, so that C, whose practice was right, might be judged to have argued less logically than A and B, whose advice might have resulted disastrously. In face of the fact that of three experts two were wholly misled by deferring too much to the established surgical tradition, while a third narrowly, and more by accident than design, escaped the like fate, it may seem a paradox to say that the diagnosis was obvious from the first. Yet I believe the statement to be simple truth, and that the rule of waiting till one is able to detect tumour and uterine fixation, whilst in many cases it may seem to work extremely well, is sure in the end to lead to trouble. By way of substitute for it I venture to suggest that in a woman of child-bearing age, sudden severe pelvic pain, with pallor and collapse, is in itself sufficient to establish a diagnosis of rupture of an extra-uterine pregnancy and to make immediate laparotomy imperative.

Stoke Newington Common, N.

Reviews and Notices of Books.

A BATCH OF ANNUALS.

1. *The Official Year Book of Scientific and Learned Societies of Great Britain and Ireland.* Twenty-eighth annual edition. London: Charles Griffin. 1911. Pp. 374. Price 7*s.* 6*d.*

2. *Whitaker's Almanack, 1912.* By JOSEPH WHITAKER, F.S.A. London: 12, Warwick-lane, E.C. Cloth, pp. 858, price 2*s.* 6*d.* net; paper, pp. 536, price 1*s.*

3. *Whitaker's Peerage, Baronetage, Knightage, and Companionage for 1912.* London: 12, Warwick-lane, E.C. Pp. 837. Price 5*s.* net.

4. *Hazell's Annual for 1912.* London: Hazell, Watson, and Viney, Limited. Pp. 592. Price 3*s.* 6*d.* net.

5. *Who's Who, 1912.* London: Adam and Charles Black. Pp. 2364. Price 10*s.*

6. *Who's Who Year Book, 1912-13.* London: Adam and Charles Black. Pp. 168. Price 1*s.* net.

7. *The Englishwoman's Year Book, 1912.* By G. E. MITTON. London: Adam and Charles Black. Pp. 390. Price 2*s.* 6*d.* net.

8. *The Writers' and Artists' Year Book, 1912.* London: Adam and Charles Black. Pp. 137. Price 1*s.* net.

9. *Amateur Gardeners' Diary and Dictionary for 1912.* London: Offices of *Garden Life.* Pp. 227. Price 1*s.* net.

10. *Live Stock Journal Almanac, 1912.* London: Vinton and Co., Limited. Pp. 344. Price 1*s.* net.

1. *The Official Year Book of Scientific and Learned Societies* contains a list of the scientific and learned societies of Great Britain and Ireland and concise information with regard to the officers of the societies, dates of meetings, conditions of membership, and the publications which they issue. In addition there are lists of papers read at many meetings, with the names of their authors, so that the "annual" forms a fairly full record of the work done in science, literature, and art from July, 1910, to July, 1911. The medical section comprises 60 pages. Other sections cognate with medicine are chemistry, biology, and psychology. The United Services Medical Society appears under the Section of Medicine, its appropriate place; but there is no cross reference to it in the Section of Naval and Military Societies, an omission to which we have on a previous occasion called attention.

2. *Whitaker's Almanack* is an indispensable book of reference for the home, the office, and, indeed, in every department of life, the information which it contains being extremely accurate and arranged in an easily accessible form. The present issue, in addition to the well-known features of the annual, contains many new articles, much additional statistical information, and is larger than the previous issue by 66 pages. Among the new matter are articles and statistics on "Labour Unrest of the World," "A Summary of Public and Private Wealth," "Trade Union Statistics," "Aviation in 1911," "The Mercantile Fleets of the World," "Suez Canal Traffic," "Boy Scout Movement," "Wages and Employment," and "Friendly Societies." In the tabular list of new books and new editions published in the United Kingdom in 1910 it is interesting, if not a matter of congratulation, to notice that out of a total of 11,705, medical and surgical publications number 316, and head the list among scientific books. The index contains upwards of 7000 references.

3. *Whitaker's Peerage, Baronetage, Knightage, and Companionage* is another reference book which holds a deservedly high place among works of its kind. The present issue has been enlarged by 25 pages, and includes a full account of the Coronation taken from official sources.

4. *Hazell's Annual*, which is in its twenty-seventh year of issue, continues to be the desk companion of many busy workers. For ready reference with regard to events of the past year, questions relating to the government of the country, education, trade, and so on, *Hazell's Annual*, which describes itself as a Record of Men and Movements of the Time, is particularly valuable to the public man and to the journalist. The index shows that the book has been revised to Nov. 25th, 1911. It may be mentioned that the Insurance Act is admirably summarised—if, indeed, it can be summarised in its present state—and in view of possible Home Rule legislation Mr. Gladstone's schemes of 1886 and 1903 are compared in parallel columns.

5. *Who's Who.*—There is no necessity to describe this well-known annual biography of living people beyond saying that it grows in size with each succeeding year, and that the information which it contains is trustworthy, being largely auto-biographical. At some time or other every educated man and woman must find it necessary to consult a work of

this kind, which not only deals with prominent personalities of the day but—what is of yet more use—also gives interesting details of less known men and women. The fulness of these details sometimes moves the reader to amusement, when he is not interested for serious reasons in learning the exploits or tastes of the individual; but when he wants such information he is extremely pleased to find it in an accessible source and a concrete form.

6. *Who's Who Year Book* is a useful supplement to the above, bearing a similar name. It contains lists of Members of Parliament, of holders of ecclesiastical preferments, of churches and chapels, of owners of winning racehorses, of Newdigate prizemen, of prominent physicians and surgeons, of managers of railways, of presidents of societies, of professors at universities, of titled American ladies, and other matters which everybody on occasion may need to look up.

7. *The Englishwoman's Year Book* will appeal to women of all ranks and all ages. The information contained deals with every department of life—education, sport, literature, philanthropy, the professions, and industries. It is an encyclopædia within its indicated limits.

8. *The Writers' and Artists' Year Book* contains lists of journals and magazines, both British and American, with details as to their character, scope, requirements, the remuneration given, and other information useful to the writer and the artist. As showing the up-to-date character of the book, it may be mentioned that there is a list of cinematograph journals, and the names of firms which accept plots for cinematograph films are also given. The book is indispensable to everyone who makes his living or part of his living by the pen or pencil, and some of the advice given or implied is very valuable.

9. *Amateur Gardeners' Diary and Dictionary.*—Amateur gardeners, of whom there are many in the medical profession, will find this a handy and useful little book. A blank page is devoted to each week of the year for notes of the work done and to be done, while facing these pages is printed information with regard to the weather, such as average rainfall, temperature, and sunshine, and the general work of the garden and greenhouse appropriate for the time of the year. Space is included for accounts and exchange of plants, and at the end of the book there is a dictionary of plants, which contains cultural directions in a concise form.

10. *Live Stock Journal Almanack.*—Not many medical men in these days can find time actively to interest themselves in farming and the breeding of live stock, but those fortunate in being able to enjoy the country life will probably find matter of interest in this annual. It contains a large amount of statistical information and illustrated articles on subjects appealing to the farmer and others, whether amateur or professional, interested in the subjects of which it treats.

JOURNALS AND MAGAZINES.

Journal of Pathology and Bacteriology. (Official Organ of the Pathological Society of Great Britain and Ireland.) Vol. XVI., No. 2. Published from the Department of Pathology, University of Cambridge. Price 7*s.* 6*d.* Yearly subscription £1 1*s.*—Dr. J. M. Beattie and Dr. A. G. Yates, of Sheffield, describe observations on Sugar Tests and Pathogenicity in the Differentiation of Streptococci. Forty-two strains of streptococci, which had been isolated from pus, joints, rheumatic and other lesions in man, were examined. The sugar-fermentation tests proposed by Dr. M. H. Gordon proved useless in their hands as a means of differentiation and classification, nor could any definite distinctions be drawn from the results of inoculation experiments on animals.

Dr. J. P. McGowan, of Edinburgh, records a series of interesting observations on an epidemic among cats, supervening on and simulating distemper, and characterised by a purulent and bloody discharge from the nose and eyes and often ending fatally. A diplococcus, hitherto undescribed, was isolated from the nose and heart blood in all cases. From many of the animals that had already suffered from distemper the author has isolated the organism which he regards as the cause of distemper; this disappeared with the onset of the second infection and was replaced by the diplococcus. Dr. A. E. Boycott and Dr. R. A. Chisolm, of London, describe a series of observations on rats regarding the influence of underfeeding on the blood. They find that underfeeding for three weeks on a diet deficient in proteid to such an extent that the animals lost one-third of their weight does not cause any wasting of the red cells or of the whole blood. Dr. Boycott makes a further contribution to the study of the Rate of Regeneration of Hæmoglobin after Hæmorrhage. After a hæmorrhage of one-third of the whole blood a large rabbit regains the normal level in about 19 days, a small rabbit in 13 days, a large rat in 6½ days, and a small rat in 5 days. The greater powers of regeneration in young animals is correlated with their more rapid growth. Rats regenerate proportionately faster than rabbits because their red cells normally have a shorter life and the marrow has to be proportionately more active to make good the normal loss. Dr. Chisolm, writing on "The Influence on the Blood of the Rat of the Presence of a Transplanted Sarcoma," finds from the exact study of 74 animals, compared with 87 normal rats, that the presence of a transplanted sarcoma usually causes a fall in the total and percentage amounts of hæmoglobin and an increase in the volume of the blood. This anæmia does not depend on the presence of ulceration, and is usually accompanied by wasting of the body tissues. There is reason to believe that with small tumours, and with small tumours only, the animal increases its hæmoglobin and its blood volume to meet the needs of the tumour.

Dr. C. H. Browning and Dr. J. Cruickshank, of Glasgow, report an elaborate study on the Action of Cholesterin and its Derivatives on Lecithin as Syphilitic Antigen and as Hæmolysin with Cobra Venom—(1) in promoting the absorption of complement with lecithin in the presence of syphilitic serum, (2) in inhibiting the lysis of red blood corpuscles by lecithin, cobra-venom. The various substances investigated vary in their action according to both the physical condition (turbidity) of the emulsion and the chemical constitution, and are not equally effective as regards the two modes of action investigated. Thus, cholesterin esters are very efficient in the syphilis reaction, but have hardly any effect on lecithin-cobra-venom hæmolysis. In both reactions cholesterin itself is most effective. Dr. Cruickshank, in a paper on the Histological Appearances Occurring in Organs Undergoing Autolysis, states that in organs undergoing aseptic autolysis at body temperature in salt solution there is great œdema of the tissues and rapid plasmolysis, nuclear changes occurring more slowly. In tissue kept in a moist chamber there is no œdema or plasmolysis, the nuclei degenerate more quickly, and the changes closely resemble those seen in necrotic tissue in the body. The changes are markedly slowed by the presence of toluol, and are almost completely inhibited by heating to 57° C. They are accelerated by staphylococci or a staphylococcus filtrate, but not by tubercle

bacilli or tuberculin. No histological signs of fat were found to appear.

Mr. C. E. Walker and Dr. H. E. Whittingham, of Glasgow, in their Further Observations on the Resemblance between the Cells of Malignant Growths and those of Normal Gametogenic Tissue, by carefully enumerating the chromosomes in a large number of dividing cells in the normal human testis, find that they can be divided into two groups, one of which tends to show about 16, the other about 32 chromosomes. The same distribution is found in malignant tumours. In inflammatory proliferation, though there are many cells with 16 and many with 32 chromosomes, the distribution is very irregular, and the distinction into two definite groups largely disappears. The authors consider that their results strongly support the essential similarity between the cells of malignant tumours and those of normal gametogenic tissue. Dr. M. J. Stewart, of Leeds, in a paper on the Histopathology of Cancrum Oris, describes five typical examples of cancrum oris which present a constant histological picture. In very acute cases there is little or no tissue reaction; in others there may be many leucocytes, plasma cells, and mast cells. Spirilla extend deeply into apparently normal tissue; fusiform bacilli do not extend so far, and necrosis of the tissues takes place only after invasion by these latter organisms. In the superficial necrotic area many cocci and filamentous organisms are found. Dr. O. Klotz and Dr. M. F. Manning, of Pittsburg, in a study of the Fatty Streaks in the Intima of Arteries, especially the narrow longitudinal pale streaks found chiefly on the posterior wall of the thoracic aorta, deals with their occurrence, nature, and significance. These streaks are most common between the ages of 11 and 30, are almost constantly present in fatal cases of typhoid fever (33 out of 35), and are common in infective conditions generally. Anatomically, there are fatty change and degeneration in the subendothelial connective tissue, and in more advanced cases also in the subjacent musculo-elastic layer. There is also more or less marked proliferation of the intima, forming a small nodule over the degenerated area, in or about which there is never any acute inflammatory reaction. These lesions usually disappear without leaving any demonstrable traces, but in some cases the proliferation of the subendothelial layer is the commencement of nodular arteriosclerosis. The condition probably has no connexion with definite atheroma of the aorta. Dr. L. S. Milne, of New York, in a study of Chronic Arthritis describes the changes found in the joints in arthritis deformans (rheumatoid arthritis), and compares them with those occurring in gonorrhœal infection, in tabes, and in experimental infections in animals.

Quarterly Journal of Microscopical Science. Edited by Sir E. RAY LANKESTER, K.C.B., F.R.S., with the coöperation of ADAM SEDGWICK, M.A., F.R.S., SYDNEY J. HICKSON, M.A., F.R.S., E. A. MINCHIN, M.A., F.R.S., and GILBERT C. BOURNE, M.A., F.R.S. November, 1911. London: J. and A. Churchill. Price 10*s.* net.—The opening paper of this number is of considerable medical interest as a contribution to the study of pathogenic amœbæ. It is divided into two parts, in the first of which Major W. Glen Liston, I.M.S., gives a very full account of certain cultures of amœbæ isolated from dysenteric lesions and other sources, while in the second part Mr. C. H. Martin, demonstrator of zoology in the University of Glasgow, describes preparations of amœbæ from Major Liston's cultures. These cultures were obtained in Bombay from (1) an abscess of the liver; (2) a dysenteric stool; (3) Bombay City tap-water; and (4) the stool of a healthy monkey. A preliminary examination of the cultures, which had been planted more than a month previously, showed that in each case all the amœbæ were encysted, and that in all they were associated with a variety of bacteria. It was next found that two types of cysts were present in the culture from the abscess of the liver, one type having a diameter varying between 6 and 8μ and the other a diameter varying between 12 and 15μ. In subcultures these forms reproduced themselves true to type—that is to say, large cysts were always formed by amœbæ which had developed from a single large cyst, while small cysts were always the product of small cysts. The two types also differed in respect to their methods of multiplication and their behaviour in saline solution. The large amœba was observed to multiply by endogenous budding as well as by division into two individuals; the small amœba, however, cultivated from the small cysts of the same culture, was never seen to give off buds; division in this case was direct or amitotic. When dilute saline solution was added to an actively developing subculture from the liver-abscess culture the large amœba always assumed a more or less rounded form, with numerous needle-like pseudopodia projecting from the surface, while the small amœba, on the contrary, almost always assumed a worm-like or gregarine shape, throwing out one or two long pseudopodia. Physiological tests failed to demonstrate any pathogenic properties in either of these two amœbæ. Mr. Martin, in his description of preparations from the above-mentioned cultures, says that the small type of amœba from the abscess of the liver and the amœba of dysentery seem to agree absolutely in all their essential features. The morphology of the organisms is illustrated by three full-page plates of drawings.

Miss Muriel Robertson contributes a paper on the Division of the Collar-cells of the Calcarea Heterocœla. She says that although this process is a typical metazoan mitosis it reveals some rather primitive features, such as the very slight development of the spireme, the absence of rays from the centrosomes and the general indistinctness of the chromosome. The organisms were contained in a kind of marine sponge. The next article consists of Observations on the Trypanosome of the Little Owl (Athene noctua), with remarks on the other Protozoan Blood-parasites occurring in this Bird, and is a long paper written jointly by Professor E. A. Minchin and Mr. H. M. Woodcock. For the purpose of this research these gentlemen spent about three months at Rovigno, in Istria, but most of their owls had to be procured from Vienna or Breslau. Of 18 birds examined 12 were found to be infected with one or more parasites—either leucocytozoon, protoseoma, halteridium, or trypanosome. After describing at least three types of trypanosome of the owl, they record their opinion that all the different forms of this organism in the blood of athene noctua belong to one and the same species, for which they propose the name trypanosoma noctuæ (Schaudinn). The succeeding paper is a lengthy one by Mr. Charles H. O'Donoghue, on the Growth-Changes in the Mammary Apparatus of Dasyurus and the Relation of the Corpora Lutea thereto. The animal chiefly investigated was the Australian native cat, dasyurus viverrinus, a small marsupial which has a breeding season once a year. After describing the formation of the mammary gland, Mr. O'Donoghue gives a full account of the changes which occur in it prior to ovulation, during pregnancy, after parturition, and when ovulation is not succeeded by pregnancy. He arrives at the conclusions (1) that the corpus luteum is a ductless gland producing a secretion (a hormone) which is the exciting cause of the growth of the mammary gland during pregnancy and at other times; and (2) that there is at present no satisfactory theory of the causation of milk secretion. Professor E. W. MacBride describes an anomaly of conformation in Echinus. The next two papers are closely related to one

another and have practically the same subject—namely, the effect which the rhizocephalan parasite, sacculina neglecta, has upon the sexual physiology of crabs belonging to the two genera inachus and carcinus invaded by it. The authors of the papers—Mr. Geoffrey Smith and Mr. Guy C. Robson—found that sacculina invariably led to an increased deposition of fat in the "liver" of the crabs, but that the sexual effects were not exactly the same in the two genera.

The Journal of Physiology. Edited by J. N. LANGLEY, Sc.D., F.R.S. Vol. XLIII., Nos. 3 and 4. London: C. F. Clay, Cambridge University Press. Nov. 20th, 1911. Price 8*s*.—In The Influence of Colloids on Diuresis, Frank P. Knowlton gives one classification of diuresis which distinguishes two kinds: one which is accompanied by increased oxygen consumption by the kidney, and therefore may be considered as due, at least in large part, to secretory activity—e.g., diuresis by injection of urea, caffeine, or Na_2SO_4; the other, even though the increase of urine is relatively enormous, is unaccompanied by any change in oxygen consumption—a phenomenon which it is natural to consider as purely mechanical, a conspicuous example being the diuresis following the injection of physiological saline solution. Among the factors associated with this mechanical production of urine are change in (1) arterial blood pressure; (2) blood flow through kidney; and (3) physical effects caused in the blood by the diuretic agent. This paper is in part an extension of somewhat similar work already published by Barcroft and Staub. Having excluded certain factors, the author's attention was directed to the question as to whether any residuum of diuresis could be attributed to changes in the osmotic pressure of the proteins in the plasma. Most of the experiments were made on anæsthetised rabbits. Elaborate tables and diagrams are given to show the effect of colloids on saline diuresis—e.g., diuresis due to injection given intravenously of a Ringer's solution. The colloids injected were salt-free gelatine (5 per cent.), gum acacia (5 per cent.), and starch. Another series of experiments deals with the influence of colloid on chloride (hypertonic solutions of NaCl, 5 per cent.) or sulphate diuresis Na_2SO_4 (15 per cent.). The author concludes that colloids which possess an osmotic pressure—e.g., gelatine and gum acacia—are effective in inhibiting the diuresis produced by normal saline solution or by hypertonic NaCl, but are largely ineffective upon the diuresis caused by Na_2SO_4. Colloids possessing no such osmotic pressure are without such action. The colloids in the concentration used caused no measurable change in blood flow through the kidney, and did not influence the gaseous metabolism in the gland. The author arrives at the conclusion that change in the concentration, and therefore in the osmotic pressure, of the blood colloids is a factor in the production of urine in the glomerulus.

A. G. W. Owen and Professor Sherrington, in their Observations on Strychnine Reversal, continue and extend the thesis that strychnine changes an inhibitory reflex to an excitatory one—a result already observed by using the knee extensor muscle, the vastocrureus. The authors' experiments were conducted on deeply anæsthetised cats. Decerebration was performed and the semitendinosus, the chief knee flexor, was isolated by appropriate nerve sections, so that it remained the only unparalysed muscle in the limb. The reversal obtains in the knee flexor as well as in the case of the knee extensor—with the ankle extensor as with the knee extensor. The next communication is from the Laboratory of Experimental Therapeutics of the University of Chicago, by Joseph L. Miller and E. M. Miller, on the Effect on Blood Pressure of Organ Extracts, the results of which amplify those already known on this subject.

The Physiological Laboratory and School of Agriculture, Cambridge, is the source of the next paper by F. H. A. Marshall, entitled "The Male Generative Cycle in the Hedgehog, with Experiments on the Functional Correlation between the Essential and Accessory Sexual Organs." The males in most species of mammalia do not exhibit the same degree of sexual periodicity as is shown by the females. The accessory glands of the male hedgehog undergo a periodic metamorphosis, which the author has investigated, partly by a series of experiments in which the animals were castrated or vasectomised, either completely or unilaterally. The results of the experiments demonstrated very clearly the existence of a close functional correlation between the essential and accessory generative organs in the male hedgehog. The vesiculæ seminales are secretory glands, and do not contain spermatozoa. Dr. Hopkins adds a note on the Chemistry of the Vesicular Fluid of the Hedgehog. We failed to notice any reference to Gley's observations on the fluid of the vesiculæ seminales of the guinea-pig.

The contribution by A. V. Hill on a New Form of Differential Micro-calorimeter for the Estimation of Heat Production in Physiological, Bacteriological, or Ferment Actions is from the Physiological Laboratory at Cambridge. It gives an account of a calorimeter—on the principle of a Dewar flask—by means of which one can determine the heat produced in long periods of time by small cold-blooded animals, by plants, or by micro-organisms. The paper by W. M. Fletcher, on the Alleged Formation of Lactic Acid in Muscle during Autolysis and in Post-survival Periods, is one that will interest organic chemists as well as physiologists.

On the much vexed question of the Innervation of the Coronary Vessels, T. G. Brodie and W. C. Cullis used an isolated mammalian heart, and compared their results with those of Schäfer, who "injected as much as 0·00015 to 0·0006 gramme of adrenalin." The authors explain the results they obtained, as compared with those of previous observers, as due to the much larger dose of adrenalin employed in their experiments. Schäfer's minimum dose was 15 times greater than that of their maximum. In the Action of Homologous Alcohols and Aldehydes on the Tortoise Heart H. M. Vernon finds that the toxicity of the alcohols increases with their molecular weight, that of iso-amyl being 23 times greater than that of methyl alcohol. This is a paper which should be interesting particularly to pharmacologists. Sokoru Oinuma, in a paper on the Question of the Presence in the Frog of Vaso-dilator Fibres in the Posterior Roots of the Nerves Supplying the Foot and in the Sciatic Nerve, finds that the posterior roots of the eighth and ninth spinal nerves in the frog contain no vaso-dilator fibres for the hind limb, but the sciatic nerve itself does.

The following are some of the titles in the Proceedings of the Physiological Society, July 22nd and Oct. 21st:—F. W. Pavy and W. Godden: Inhibition of Post-Mortem Production of Sugar in the Liver and of Certain Forms of Glycosuria by the Intravenous Injection of Dilute Solutions of Sodium Carbonate. E. L. Collis and M. S. Pembrey: Observations upon the Effects of Warm Humid Atmospheres on Man. G. R. Mines: The Influence of Certain Ions on the Electric Charge of Colloids, and its Bearing on Comparative Physiology (preliminary communication). Charles H. O'Donohue: The Relation Between the Corpus Luteum and the Growth of the Mammary Gland. A. G. Levy: Sudden Death under Light Chloroform Anæsthesia (a further communication). Joseph Barcroft and Franz Müller: The Formation and Estimation of Methæmoglobin.

SAVILL MEMORIAL FUND.—The Savill Memorial Fund has now reached £355, and the treasurer, Mrs. Hardy, 18, Iverna-court, Kensington, W., will be glad to receive any further contributions. The committee has decided to give a yearly medal and found a scholarship in clinical neurology with the fund, which still remains open.

THE LANCET.

LONDON: SATURDAY, DECEMBER 30, 1911.

THE ANNUS MEDICUS 1911.

YEAR by year we carry out a medical stock-taking at Christmas-time, and year by year it grows more difficult to know what to include or what to exclude. But we are happy to know that such an annual summary, however brief, is of service to many of our readers, and that especially it is useful for future reference. We make little attempt at prophecy: it is well-nigh impossible, unless courage be carried to rashness, to pick upon any given piece of scientific work during the year of its record, and point to it as the beginning of a new principle or the embryo of a method of treatment with which great things will be wrought. Our present stock-taking possibly leaves out of notice some innovation destined in the near future to have much significance; and possibly again it may attribute undue importance to something which is on the edge of being superseded. A *résumé* of this nature, whatever pains be spent upon it, must necessarily fall short of completeness, but we are encouraged by our readers to continue the custom of our predecessors and to add another chapter to the history of modern medicine that has been compiled in these pages, and in its present form, for half the lifetime of THE LANCET—now becoming an impressive period. Year by year the chapters have grown longer, and space forbids us to make each of them more than an expanded index, but it is, we trust, a discriminating index.

MEDICINE.

Tuberculosis.

THE subject of pulmonary tuberculosis has again attracted a large amount of attention, not only from members of the medical profession but also from legislators and from the public generally. The Public Health (Tuberculosis) Regulations, 1908, provided for the notification of the disease occurring amongst the inmates of Poor-law institutions or amongst persons under the care of district medical officers. An Order which came into force in May of this year provided for the notification of pulmonary tuberculosis occurring amongst the in-patients or out-patients of those hospitals supported wholly or in part by voluntary contributions. According to these regulations a medical officer of any hospital, within the period of 48 hours after his first recognition of the malady in a person upon whom he is in medical attendance at the hospital, must complete, sign, and transmit a notification of the case, in the form shown in the special schedule to this Order, to the medical officer of health for the area within which the hospital is situated. The results obtained by these regulations have evidently proved satisfactory in the opinion of those who are able to judge, for new regulations have now been issued completing the system of notification, and hereafter it will be the duty of every medical practitioner, with certain exceptions specified in the regulations, to notify every case of pulmonary tuberculosis occurring in the course either of his public or of his private practice. The new regulations come into force on Jan. 1st next. The result of the practical application of this scheme will be watched with interest, but some time must elapse before a judgment can be formed as to the effect of compulsory notification on the incidence and death-rate of the disease.

In delivering the Presidential Address before the British Medical Association at Birmingham Professor R. SAUNDBY drew attention to the advantages and importance of the coöperation of medicine and the public in the campaign against tuberculosis. He pointed out that the practical measures which are being organised to deal with tuberculosis are probably to be regarded as the outcome of the fact that everyone now knows that consumption, the commonest form of tuberculous disease, is communicable through the agency of dried sputum from cases of this disease. He also stated that if it can be still further brought home to the public generally that the disease is in a large majority of cases curable if recognised early and appropriately treated, and that it is preventable and not an inevitable result of family predisposition, there can be little doubt that an effective and comprehensive campaign, both curative and prophylactic, will soon be inaugurated. He likewise pointed out the significance of the fact that the diminished incidence of pulmonary tuberculosis was concurrent with increasing sobriety, better housing, growing education, and the social and moral elevation of the people. The establishment of dispensaries for the treatment and guidance of patients suffering from consumption will doubtless prove of great value.

As part of the National Insurance Act Mr. LLOYD GEORGE has provided a sum of £1,000,000 for the maintenance of sanatoriums, and in that way removes from the scope of domiciliary treatment a considerable proportion of tuberculous patients who would otherwise make serious calls upon the sum available for domiciliary medical attendance and provision of drugs. He has also allotted £1,500,000 for the erection of sanatoriums in those districts where such institutions are desirable.

The final report of the Royal Commission appointed to inquire into the relations of human and animal tuberculosis was issued during the year, and is a document of great scientific interest and of extreme practical importance. In regard to the question whether tuberculosis in animals and man is one and the same, the conclusions arrived at are that the human and bovine types of bacilli are morphologically indistinguishable, but that they differ appreciably in their cultural characters and in their pathogenic effects in various animals. The slight cultural differences are considered by the Commission as insufficient to establish the two types as distinct organisms, and it prefers to regard them as varieties of the same bacillus, and to consider that the lesions which they produce, whether in man or other animals, are manifestations of the same disease. The reply to the second term of the reference to the Commission—viz., whether animals and man can be reciprocally infected with tuberculosis—is very definitely and unequivocally in the affirmative. The third term of the reference—viz., to determine under what conditions, if at all, the transmission of tuberculosis from animals to man takes place, and what circumstances are favourable or unfavourable to such transmission—is a very wide one. The conclusion of the Commission was that, whatever may be the source of tuberculosis in adolescents and in adult man, there can be no doubt that a considerable proportion of tuberculosis affecting children is of bovine origin. Even in adolescents and adults so large a proportion of the cases investigated—i.e., 5 out of 55—showed the presence of the bovine type

as to indicate that the same avenues of infection are possible at other periods of life than childhood. The importance consequently of strict administrative measures to deal with the prevention of the danger from infected milk and meat is urged by the Commission, whose attitude serves to illustrate the important practical bearings of the work.

Tuberculin has been extensively employed in the treatment of tuberculosis, and during the past year numerous observers have recorded their experience. The method of administering the remedy and the variety to be employed have received especial attention. Considerable difference of opinion still exists, but there is a steadily growing belief that tuberculin is of real value, especially in early cases of the pulmonary variety. The theory that the success attained in treating suitable cases of this disease by means of graduated labour is due to auto-inoculation is also gaining ground.

The procedure of producing artificial pneumothorax in the treatment of pulmonary tuberculosis has again been revived in this country. Dr. CLAUDE LILLINGSTON, in an article contributed to THE LANCET of July 15th, described the practical details of the method, together with the indications for its employment. In view of all the risks and complications of the operation we cannot but feel that this plan should at present be restricted to severe febrile cases which ordinary therapeutic measures are failing to influence favourably, and further, that its tentative character should be carefully explained to the patient and his friends. It is obviously not a procedure to be lightly recommended, and until much more information is forthcoming, both in regard to its immediate and remote results, it is impossible to form any judgment of its value.

An interesting report on how tuberculosis is spread in India was issued by Dr. J. A. TURNER, executive health officer, Bombay. In addition to the danger of infection by sputum and the flesh and milk of animals, he laid stress on another possible source by which the malady might be spread—namely, the contamination of food matters by individuals and animals the subjects of active tuberculous disease. He thought that cattle in India are affected, but only to a limited extent. His investigations led him to believe that the habits of the natives undoubtedly tend to convey the bacilli, and that the difficulties in the way of prevention must prove even greater than in England.

Measles.

In the early part of the year measles assumed an epidemic form in London and many great centres, and once more proved the remarkable tendency of the disease to display fluctuations in major waves of prevalence, over and above its well-known predilections for certain seasons of the year, and its rise and fall in minor waves, often of biennial rhythm. The number of deaths in one week in London rose to 197, the highest total weekly number of deaths from measles ever recorded in the metropolis. This very serious mortality was the more emphasised because other infantile maladies have in recent years shown marked abatement. The Metropolitan Asylums Board decided to utilise its hospitals for the treatment of certain cases of measles; this was a wise proceeding, as tending considerably to reduce the case mortality, and the children of the very poor could be far better cared for in these institutions than in their own homes. A useful memorandum was issued by the medical officer of the Local Government Board in which the difficulties and possibilities as regards control of measles were fully discussed. The greatest difficulty is, perhaps, the recognition of the disease. Medical attendance is but rarely sought for this complaint among the poorer classes, and without such attendance recognition and notification cannot follow. There is, however, one important source of information as regards measles which has not so far been utilised as fully as it might have been. The school attendance officer is in a very favourable position to hear rumours as to the possible existence of measles in any given family, and an efficient coördination between himself and the local medical officer of health might bring to light suspected cases and lead to the exclusion of patients and families from schools, or even to the closure of certain sections of schools. The high mortality is brought about largely by the result of inexperienced nursing and treatment, and if medical advice could be sought at an early stage, or the children in certain instances be removed to an isolation hospital and properly treated, many lives might be saved.

Diphtheria.

The probable influence of diphtheria carriers has been the most debated point in connexion with this disease. Dr. ANGUS G. MACDONALD contributed an interesting paper to our columns on the subject. As a result of his inquiries he came to several conclusions, of which the following are the most important. Carriers are found at all ages and of either sex. In many cases it cannot be said that one case was actually derived from another, for the detected carrier may have given the disease to those around, or may only have just received it. The presence or absence of an obvious pathological condition is no criterion of the fact of a carrier, of the length of carrier life, or of virulence. The length of carrier life seems to have no effect on virulence; bacilli have been demonstrated to be virulent after four or eight months in the ear and nose of different individuals. Carriers are found amongst those most intimately associated with other carriers or cases: at home between mother or nurse and child, and child and child who play together; at school the carriers found are few and always closely associated (in play and not necessarily in school-room proximity) with some other carrier or case. Dr. MACDONALD maintains that the control of diphtheria depends on the control of the carrier. He thinks that the carrier should be notified as a case of diphtheria, no matter of what age or sex, and due quarantine and observation would be maintained until satisfactory demonstration of the disappearance of the pathogenic bacillus. As everything points to the conclusion that the bacillus is essentially a human parasite, he believes that a determined attack on the lines of thorough bacteriological investigation should result in stamping out diphtheria altogether from the land.

Acute Poliomyelitis.

An epidemic which occurred in Devon and Cornwall during the summer months drew attention to an infective malady which has been but little studied in this country. Early in August a notice appeared in one of the Devon papers of an outbreak of "spotted fever" in the area around Holsworthy. Later in the same neighbourhood cases were recorded of acute poliomyelitis, and some difficulties of diagnosis arose. At a meeting of the Devon county education committee on Sept. 8th Mr. G. ADKINS, the county medical officer, gave an account of the outbreak of acute poliomyelitis in various parts of the county. He stated that 25 schools had been closed, and that the disease was present in 12 of the 52 districts of the county. There had been 80 cases altogether, and 16 deaths had occurred. He also stated that three definite cases of "spotted fever" were known amongst those reported. We took the opportunity[1] of briefly explaining the main differences between cerebro-spinal fever and acute poliomyelitis, and indicated the manner in which they may be communicated. Recently a memorandum has been issued by the Permanent Secretary of the Local Government Board recommending the notification of both these diseases.

Plague.

The reports and papers on suspected cases of human plague in East Suffolk and on the epizootic of plague which

[1] THE LANCET, Sept. 23rd, p. 896.

attacked rodents in that district during the autumn and winter of 1910 possessed the deepest interest for all epidemiologists. The epidemiological and administrative sides of the outbreak were dealt with by the late Dr. H. T. BULSTRODE, while the flea fauna of the rats and rabbits, together with the species of the rats found, were reported on by Dr. C. J. MARTIN and Mr. SYDNEY ROWLAND, of the Lister Institute. Rat plague had probably been prevalent in some degree in this neighbourhood from 1906, and perhaps earlier, and it is a matter of great interest to note that, notwithstanding this widely prevalent epizootic, there were only from 1906 onwards three, or at most four, primary cases of human plague, the remainder being secondary cases. This relative immunity is probably in large measure to be accounted for by the different habits of the brown and the black rat, and by the circumstance that not one example of Pulex cheopis, the flea of the black rat, was discovered. Further, as Dr. MARTIN and Mr. ROWLAND show, 50 per cent. of the rat-flea population consisted of a flea which apparently bites man but rarely. The remainder of the rat-flea population was composed of Ceratophyllus fasciatus, which does not bite man very readily—not nearly so readily as does the rat-flea of India. There is, therefore, left only about one man-biting rat-flea to every two rats, a flea prevalence which, according to the work of the Indian Plague Commission, is too small to give rise to a human epidemic in India. In Dr. BULSTRODE'S view, a study of plague literature points to the conclusion that the pneumonic type played a more important part in the diffusion of plague in past epidemics than is generally believed. In the report a detailed account is given of the mysterious outbreak which occurred on the banks of the Orwell in the winter of 1909 to 1910, and which involved eight persons with five deaths. This outbreak resulted in two post-mortem examinations and three inquests, there having been, it seems, some suspicion of poisoning. But this suspicion is certainly dispelled by the searching examination to which Dr. BULSTRODE subjected the evidence, and it is clear that a communicable malady, having the incubation period and many of the signs and symptoms of plague, was in question. Whether this was actually an outbreak of bubonic and septicæmic plague cannot be certainly determined, but the outbreak is best explained upon the theory that the disease was plague.

Anthrax.

A report was published by the Worshipful Company of Leathersellers on the Incidence of Anthrax amongst those Engaged in the Hide, Skin, and Leather Industries, with an Inquiry into Certain Measures aiming at its Prevention. The report was drawn up by Dr. CONSTANT PONDER, the bacteriologist to the Company's technical college, who had been engaged in investigating industrial anthrax. From his investigations several interesting and important conclusions were drawn. Some 40 per cent. of all the cases of anthrax in British leatherworkers are due to handling Chinese or East India goods. The cutaneous infection would seem to be the most common, 82 per cent. of the cases exhibiting pustules on the head or neck. No case of pulmonary anthrax infection, such as occurs amongst the Bradford wool-workers, had been reported amongst those working in hides and skins, and only two cases of the intestinal form had occurred in the last seven years. The point in Dr. PONDER'S report which is well brought out, and upon which great stress is laid, is the fact that the infective material—i.e., the anthrax spore—is most likely to be found in discharges dried upon the fur, and at the cut ends of subcutaneous capillaries. He has carefully studied the many and varied methods which have for their object the destruction of the infective materials. The difficulty is to find a plan which will destroy the organisms and their spores without harming the hides and skins. It is remarkable that no case of anthrax infection has ever been traced to wet-salted hides, and Dr. PONDER therefore suggests that all skins and hides should be imported in the wet-salted state. This is a plan which has much to recommend it from the point of view, not only of the leather-workers themselves, but also of the brokers and even of the shippers.

Ankylostoma Infection.

Of diseases due to animal parasites few within recent years have attracted so much attention as the condition of ankylostomiasis, and in the Milroy lectures delivered before the Royal College of Physicians of London Dr. A. E. BOYCOTT gave an excellent account of the present knowledge on the subject. The parasite has been found very widely distributed in both hemispheres, and many obscure forms of anæmia have eventually proved to be due to ankylostomiasis. Dr. BOYCOTT drew an important distinction between ankylostomiasis and ankylostoma infection. Any individual who harbours these parasites in his intestine is a worm-carrier and is thus the subject of ankylostoma infection, but he may show no evidence of this other than the passage of ova and the presence of an eosinophile reaction in his blood; whereas if the number of parasites be sufficient, grave anæmia, dyspepsia, and other disabling symptoms occur, and the patient is then the subject of the disease ankylostomiasis. The worm-carrier may be as important a factor in the dissemination of the disease as the bacteria carrier is in connexion with diseases such as typhoid fever and diphtheria, unless adequate precautions are taken. The essentials for the production of the infection by ankylostoma are fæcal contamination of the soil with ova of the parasite, sufficient moisture to prevent their desiccation, and temperature conditions favourable to their development. In the tropics these conditions are almost invariably to be found, and the disease spreads so widely that it is estimated that it may reduce four-fifths of the population to a permanent state of chronic ill-health, since re-infection is constantly occurring. In regard to the modes of infection, LOOSS'S observations that the encapsuled larvæ enter the skin, reach the lungs, pass up the trachea and down the œsophagus have been generally confirmed. Dr. BOYCOTT believes that mouth infection can and does occur, and stated that he was accidentally infected by this channel himself, having failed to infect himself by the skin route. It is generally admitted, however, that the latter is the more usual mode of infection, and this discovery has proved of value in the preventive treatment of the infection.

Rheumatoid Arthritis.

In delivering the Hunterian lecture before the Royal College of Surgeons of England Mr. KENNETH W. GOADBY made some suggestive observations on the association of disease of the mouth with rheumatoid arthritis and certain other forms of rheumatism. In a preliminary survey of the subject he remarked that a large number of cases of arthritis deformans, using this term in its inclusive sense, are now recognised to be of infective origin, others are of definite neural origin, but between the two are a considerable number which, according to some observers, may be infective, according to others atrophic, neural, or even idiopathic. He called attention to the presence of various so-called rheumatic symptoms in persons subject to disease of the jaw, particularly the type of disease known as pyorrhœa alveolaris and associated with a discharge of pus from the gum margins and rarefaction of the alveolar process, and frequently the body of the bone. He gave an account of his own researches on the especial relation of rarefying alveolar osteitis to arthritis deformans, which are of considerable

value and interest. He isolated several micro-organisms from the pus obtained from the gum margin and found that one in particular seemed to give more variation in its opsonic index than any of the others. It was found on careful examination that the organism in question differed very much in its general morphology, and in a certain number of other particulars, from the ordinary streptococcus of the mouth. In conclusion Mr. GOADBY said that his contribution to the study of arthritis deformans coincident with alveolar osteitis does not seek to establish a specific organism as the etiological factor in all cases of rheumatoid arthritis, infective fibrositis, muscular rheumatism, and so on, but that in diseases of the jaw, especially rarefying alveolar osteitis, a strepto-bacillus is present, pure cultivations of which inoculated into or around the knee-joints of rabbits have produced symptoms similar to and indistinguishable from arthritis deformans; that in such disease of the mouth and jaws the treatment of the disease locally and by means of autogenous vaccine prepared from the strepto-bacillus has been associated with amelioration and disappearance of the arthritic symptoms in a greater number of instances than can be ascribed to fortuitous coincidence.

Polycythæmia and Plethora.

Within recent years many interesting results have been obtained in regard to the pathology of the blood by studying its cytological characters. Polycythæmia and plethora have been especially investigated by Professor H. SENATOR, of Berlin, and he has published an interesting work on the subject. Excluding secondary and physiological conditions, there are two forms of primary or idiopathic polycythæmia. One, first described by H. VAQUEZ, characterised by cyanosis, enlargement of the spleen, and polycythæmia, is generally known as polycythæmia rubra megalosplenica; the other is called Geisböck's disease or polycythæmia hypertonica; it has been less often observed, and only about a dozen undoubted cases are on record. The symptoms are not unlike those of the splenomegalic form, but in about half the cases apoplectic seizures occur and chronic nephritis and arterio-sclerosis are much more frequently apparent. The patients usually present a typical apoplectic habit of body.

Diseases of the Heart.

In delivering the Oliver-Sharpey lectures before the Royal College of Physicians of London Dr. JAMES MACKENZIE dwelt on the significance and treatment of heart failure. He described in plain language the meaning of the term "fibrillation of the auricles," and pointed out that the recognition of this condition and of the phenomena accompanying its onset presents the subject of the most common form of heart failure in an entirely new light, and affords ground on which a sound prognosis and a natural therapy can be based in many obscure cases. Dr. MACKENZIE maintained that heart failure simply means an inability of the heart muscle to maintain the circulation, but he was of opinion that the methods usually employed to estimate the inefficiency are inadequate. In the course of his lectures he described in detail the methods of examination which should be carried out, and concluded that the only real test of the integrity of the heart muscle is its power to respond to effort, holding that the amount of effort that can be undertaken without distress affords a basis for estimating the degree of impairment. Passing on to those conditions in which indications of heart failure actually exist, his remarks on treatment were based on the contention that failure arises because the "period of rest" cannot restore a sufficient amount of work force, the essential principle of treatment becoming self-evident—namely, rest. Rest may be secured for the heart by actual physical rest assisted by those drugs which procure the effects of rest by causing the slowing of the heart's rate; such drugs are, of course, to be found in the digitalis group.

The subject of cardio-vascular degeneration was fully considered by Dr. J. MITCHELL BRUCE in the Lumleian lectures delivered before the Royal College of Physicians of London. In considering the treatment of this condition he laid stress on the importance of ascertaining the cause of the degeneration. He drew attention to certain types of cases, classifying them under certain heads—viz., syphilitic disease of the heart and aorta, glycosuric cases, gout and cardio-vascular degeneration, physical strain, and nervous stress. Dr. BRUCE maintained that the subject of treatment appeared in a more satisfactory light when considered under the above indications than when cardio-vascular degeneration is regarded from the point of view of a single substantive disease. Some of the causes mentioned can be directly treated, whilst others demand great tact and discrimination on the part of the physician.

Diseases of the Lungs.

In the annual oration delivered before the Medical Society of London Dr. W. PASTEUR chose as his subject "Post-Operative Lung Complications." He showed that deflation of the pulmonary bases, resulting from reflex inhibition of diaphragmatic movement, is an essential, if not the chief, factor in the causation of post-operative pneumonia, and that the rôle of the anæsthetic is only a very secondary one. He placed before his hearers figures which proved that these after-effects are far from rare, and that in the present confused state of the knowledge concerning them mistaken diagnoses are probably of frequent occurrence. Dr. PASTEUR contended that in order to clear up the complex nature of these accidents and to arrive at a more reasonable classification of post-operative lesions it was necessary that the lungs should be carefully examined by a competent observer and the exact position of the heart beat noted before every abdominal operation. In this way alone would it be possible to appreciate the slight changes in the breath sounds, in the respiratory movements of the chest, or in the position of the apex beat, which indicate the onset of trouble, and often give a sure indication of its nature. Dr. PASTEUR said he was convinced that a good deal could be done in the way of preventing or alleviating many of these troubles, but before this could be achieved with any hope of success an accurate diagnosis of after-effects of operations on the lungs must be established.

Diseases of the Nervous System.

Dr. F. W. MOTT delivered an interesting series of lectures on heredity before the Royal Institution. In the last lecture he considered heredity and insanity. He maintained that hereditary predisposition is the most important factor in the production of insanity, imbecility, and epilepsy, and emphasised that it is the *tendency* to nervous and mental disease, generally speaking, which is inherited. This may be termed the neuropathic taint. He believed that alcohol is a powerful coefficient, but not of itself the main cause, in the production of insanity, except in the rather infrequent cases of alcoholic dementia. He stated that certain types of insanity may be transmitted with greater frequency than others. This has been termed "similar heredity." The types are: periodic insanity (also termed "manic-depressive"), delusional insanity, and epilepsy. The general rule, however, is for a different type to appear. He further was of opinion that recurrent insanity is probably the most potent cause of insane inheritance, owing to the fact that patients are not segregated for any length of time. Facts tend to support the belief that the recurrent types of insanity during lucid intervals may breed a stock of potential lunatics and paupers.

Lectures of the Year.

The Lumleian lectures were delivered by Dr. MITCHELL BRUCE on a Clinical Study of Cardio-Vascular Degeneration. We have already referred to some of his remarks under the heading of Diseases of the Heart. Dr. A. F. HERTZ was the Goulstonian lecturer, selecting as his subject "The Sensibility of the Alimentary Canal in Health and Disease." He concluded that the alimentary canal from the commencement of the œsophagus to the junction of the rectum with the anal canal is completely insensitive to tactile stimulation. He also showed that the mucous membrane of the œsophagus and stomach is insensitive to stimulation by dilute hydrochloric acid and certain dilute organic acids. In discussing the causation of fulness and distension, Dr. HERTZ contended that fulness and distension are due to a slow increase in tension exerted from within on the circular muscular fibres of the stomach and intestine. The muscular coat is stretched and thus a form of muscular sense is constituted. In considering the causation of actual pain in the various parts of the intestinal canal he arrived at a similar conclusion—namely, that the only immediate cause of true visceral pain is tension; this is exerted on the muscular coat of hollow organs and on the fibrous capsule of solid organs. The Croonian lectures were delivered by Dr. HENRY HEAD on the work carried out by himself and Dr. GORDON HOLMES on Sensory Disturbances from Cerebral Lesions. The Bradshaw lecture was delivered by Dr. GRAHAM STEELL, the subject being "Intra-thoracic Tumours and Aneurysms in their Clinical Aspect."

We have referred to the Milroy lectures delivered by Dr. BOYCOTT on Ankylostoma Infection and to the Oliver-Sharpey lectures delivered by Dr. MACKENZIE on Heart Failure. Dr. C. THEODORE WILLIAMS was the Harveian orator, his subject being "Old and New Views on the Treatment of Consumption."

SURGERY.

The Vermiform Appendix.

The surgery of the abdomen still remains the most important branch of the science, and the appendix has not lost its place of interest in the eye of the surgeon. The question is still widely debated whether it is advisable for the surgeon to operate immediately on every case of appendicitis as soon as it is seen, or whether he may safely postpone the operation to the "interval," when it is generally agreed that the risk of operation is very much less. It is at least a curious fact that on this point there should be so much difference of opinion, and it is also curious that nearly all those surgeons who are opposed to immediate operation live in London. There is, indeed, much to be said on both sides, but the fulminating cases which lead rapidly to death cannot, as a rule, be distinguished from mild cases. Such cases can only be saved by an immediate operation; fortunately, they are rare, but they do occur, and sometimes when they are least expected. Dr. R. E. HALAHAN has reported a case which is extremely apposite. A man, 24 years of age, had some colicky pains, but he was able to do his work, though with returns of pain. A day's rest in bed was followed by so much improvement that he considered himself well, and it was only on persuasion that he travelled to Buenos Aires to visit the British Hospital. The journey took 17 hours, but during it he felt practically well. When he was admitted into the hospital his pulse was normal and his tongue was clean, but a slight attack of appendicitis was diagnosed, and as he lived far from medical aid he was advised to have the appendix removed at once, even though the attack appeared to be subsiding. When the appendix was exposed it was found to be gangrenous for most of its length, and it was bathed in foul pus. The patient recovered, but it can hardly be doubted that if the operation had been postponed the case would have ended fatally. Mr. H. J. PATERSON has drawn attention in the columns of THE LANCET to the hidden dangers of appendicitis, and Mr. E. M. CORNER has shown how impossible it is in many cases to diagnose even gross lesions of the appendix. A case of much interest was recorded by Dr. D. D. MALPAS, for it is an account of his own plight. Some 20 years ago he had an attack of appendicitis, from which he recovered slowly under rest. In October, 1910, for three or four days he had slight pains in the right iliac fossa which he ascribed to disease of the appendix, but as he was travelling at the time and as the pains passed off in a few days he did not pay much attention to them. A month later he felt ill, with a little iliac pain, but his temperature was subnormal and the pulse was only 68, and he was able to pay visits. Though the symptoms were in no way urgent, Dr. DE LOSTALOT, of Biarritz, decided to operate, and at the operation a large quantity of clear gelatinous fluid escaped and the appendix was found perforated and surrounded by a yellow gelatinous mass which was apparently the result of the secretion of mucus by a small polypoid adenoma growing in the interior of the appendix. In this case the mild symptoms present gave no suggestion of the severity of the lesion. Another striking case of rapid and severe perforating appendicitis in which relief from pain had occurred before operation was recorded by Dr. F. W. FORBES-ROSS and Dr. QUINTON CHALMERS. The relief from the previous acute pain was probably due to the perforation of the appendix and the relief of tension, for acute general peritonitis had already started when the operation was performed, against the decided opposition of the patient. Recovery followed the operation, at which a large perforation was found, and the abdomen contained much thin pus.

At one time it was thought that the concretions which are so often found in the appendix were foreign bodies, but after their true nature was pointed out very little attention has been paid to foreign bodies in this situation, and some surgeons seem to be sceptical as to their occurrence. Mr. L. A. BIDWELL has contributed a paper in which he has described a number of cases in which he has found foreign bodies in the appendix. In three cases he found a small shot, in one a small piece of glass; hairs were not uncommon, sometimes from toothbrushes, and sometimes from paint-brushes which had been sucked. The seeds of strawberries, raspberries, and figs often occurred; grape seeds have also been found, and in one case a thorn from a rose tree was present. Fragments from eggshells and pieces from an enamelled saucepan were also discovered. Mr. BIDWELL considers that a foreign body is to be found in about 20 per cent. of all cases of appendicitis if a careful search is made.

Mr. H. J. PATERSON has drawn attention to the fact that appendicitis is by no means rarely present, although no signs of the affection have manifested themselves, and, in fact, that very marked lesion of the appendix may be present although there have never been any signs of an attack. The most typical symptom present in such cases is pain following the taking of food; it is generally referred to the left of the middle line and sometimes it radiates towards the right iliac fossa. A pain of this character may be attributed to duodenal ulcer, and, in fact, the two lesions are often associated. In two-thirds of the cases in which Mr. PATERSON had operated for duodenal ulcer he had found appendicitis also. He suggested that the duodenal ulcer was the result of toxic absorption from the appendix or from the large intestine.

Intussusception of the Vermiform Appendix.

Intussusception of the vermiform appendix is decidedly rare. Mr. H. M. COOPER has reported a case of this condition which occurred in a boy 10 years old. The child had pain and sickness after a tea party, but these subsided after an aperient; the symptoms recurred, however, eight days later.

The child looked ill, and there was some tenderness in the right iliac fossa, but the bowels were open. The next day the pulse was 120 and he had much pain in the iliac fossa with vomiting. When the abdomen was opened by Mr. G. R. TURNER no appendix could be seen, but a mass was felt inside the cæcum. The cæcum was laid open and then it was seen that the appendix lay within the cæcum completely intussuscepted and gangrenous. It was removed and the child recovered.

Even rarer than intussusception in the child is the same condition in the adult. Mr. JOHN H. WATSON, of Burnley, has reported a case. The patient was a weaver, 18 years old. After lifting a heavy beam he felt a severe pain in the lower part of the abdomen; it was so severe as to prevent his resuming work for some hours, but he went to work the next day. The pain continued at intervals for a fortnight, when a distinct lump was felt, but the patient was kept under observation for four weeks, and then as the symptoms did not mend he was admitted into hospital. It was then evident that he was suffering from chronic obstruction, and an operation was undertaken. When the abdomen was opened a large intussusception was found involving the greater part of the colon. All but 4 inches could be reduced by manipulation, and it was found necessary to resect the part that could not be reduced. The divided ends were closed, a lateral anastomosis was performed, and perfect recovery followed. When the excised portion was examined it was found that the starting-point of the intussusception was the appendix, which had apparently become cystic previously.

Foreign Bodies in the Stomach.

Cases of the presence of foreign bodies in the stomach are not at all rare, but it is seldom that such a case as that recorded by Dr. A. H. VANDERVIT and Dr. H. P. MILLS is reported. A mulatto woman, aged 33 years, was admitted into an asylum for acute mania ending in dementia, and she died seven years later, but she had never had any signs of disease of the digestive system. She was often seen to pick up nails and pins, but was never seen to swallow any. At the necropsy the stomach stretched down to the left iliac fossa in the form of a long pouch, in which lay a mass of foreign bodies, weighing 5 lb., and consisting of more than 1400 nails, screws, thimbles, and other objects. Some other foreign bodies had made their way through the wall of the stomach and had caused the formation of adhesions.

Mr. WILFRED BALGARNIE has recorded a case in which a woman had suffered from severe pain and very troublesome vomiting for five years, and at last, as rest and milk diet gave no relief, the abdomen was opened and a pin was found sticking in the small omentum; it was removed, recovery followed, and there was no return of the symptoms. Dr. I. D. CHEPMELL has also given particulars of a very similar case which occurred in his practice in Paris more than 50 years ago. A baby, about 18 months old, screamed whenever he was touched, and it was evident that there was a specially tender spot in the upper part of the abdomen. A small incision was made over this spot and a needle and thread were removed, with complete relief of the pain. The relation of this case in THE LANCET reminded Dr. EDWARD LIDDON that 60 years ago, when he was clinical clerk to Dr. BENTLEY TODD and Dr. LIONEL BEALE was house surgeon, a woman was admitted complaining of obscure gastric symptoms, and a small painful spot was found in the epigastrium. A small incision allowed a small needle to be extracted, and a day or two later another was removed in the same way. During the ensuing four or five weeks 43 needles in all were removed. The patient was very neurotic, and it was not possible to discover exactly how the needles had reached the position in which they were found.

Rupture of Abdominal Viscera.

A very useful piece of work has been carried out by Mr. A. RENDLE SHORT, who has analysed the cases of serious abdominal injury received into the Bristol Royal Infirmary during the 10 years ending 1909. There were 30 cases in all, but cases brought in dead and most of those in a dying condition were excluded from the series. There were 8 cases of ruptured liver, and 2 of these recovered—one of these was not seen until two days after the injury and nothing was done, while in the other the rent was packed with 3¼ yards of gauze. There were 6 cases of ruptured intestine, and of these 4 recovered. In one case the jejunum was torn right across; the operation was performed six hours after the injury, and end-to-end anastomosis was done, with a successful result. There were 3 cases of ruptured spleen, and all of them proved fatal; in each of the cases the patient was not admitted until some hours after the operation, and in one case two days had elapsed. Of 6 cases of ruptured kidney 3 recovered; in one of the fatal cases the liver was also ruptured. There were 5 cases of ruptured bladder, and 1 recovered. The most striking fact shown by this series of cases is that in every case of rupture of an abdominal viscus in which the pulse-rate on admission exceeded 100 per minute the patient died within 24 hours. Increased rapidity of pulse is present in most cases of serious injury, but in one case of ruptured liver it fell from 84 to 62.

Rupture of the Large Intestine from Compressed Air.

The use of compressed air in machinery has led to a number of accidents in which the hose containing the jet of compressed air has for a joke been turned against a companion. In some of these the current of air has been directed to the mouth, but 16 cases have been collected in which the stream of air has been turned towards the anus, though the hose has not necessarily been placed in contact with the clothes, but the pressure of the air has been so great that it has forced the anal sphincter and caused rupture of the sigmoid flexure or other part of the large intestine; the rupture may be multiple. The mortality is very high, for 13 of the 16 cases died. Nine cases were not operated on, and they all died, but of the 7 cases in which a laparotomy was performed 3 recovered. It is clear that the abdomen should be opened at once. An important paper on this subject has been written by Dr. ANDREWS.

Complete Gastrectomy.

Cases in which the whole of the stomach has been removed by operation are still sufficiently rare to make the record of any case well worth noticing, and the after-history is especially interesting. Mr. B. G. A. MOYNIHAN in 1907 described in THE LANCET a case in which he had performed this operation, and now he has recorded the post-mortem examination. The patient lived three years and eight months after the operation. He was quite well till a year before death occurred, but then he began to show signs of profound anæmia. Under treatment he improved, but before long he began to fail again and grew weaker, with loss of appetite and occasional vomiting, and at last he died. At the necropsy the peritoneum was found to be free from disease, although there were some old fibrous adhesions between the beginning of the jejunum and the scar in the anterior abdominal wall. The lower end of the œsophagus was anastomosed to a loop of jejunum, which had been brought through the transverse mesocolon. At the seat of the anastomosis and for a short distance beyond the jejunum was dilated though the duodenum was of its normal size. As there was a complete absence of any recurrence of the new growth and he survived for four years the result may be considered very satisfactory.

Pancreatic Cyst.

Dr. D. I. CONNOLLY has reported a case of pancreatic cyst

in a girl 14 months old. She had never had a day's illness till three or four days before admission into hospital, but then the child refused food and diarrhœa set in. On examination of the abdomen there was resistance in the right hypochondrium. On the second day after admission slight jaundice appeared, the abdomen was more distended, and a definite rounded tumour could be made out. The jaundice deepened, and the child developed an irregular temperature mostly above 102° F., and on the tenth day after admission she died. At the necropsy a cyst was found arising from the head of the pancreas, of which only the tail was left. The condition is extremely rare and was well worth recording.

Intestinal Obstruction.

Mr. EDMUND OWEN has described a case of intestinal obstruction caused by gall-stones. The patient was a lady, aged 60 years, who was suffering from violent abdominal pain and uncontrollable vomiting of one day's duration. She acknowledged that for about ten years she had suffered from sharp attacks of pain in the upper part of the abdomen recurring about every second week and lasting 24 hours, though in one attack the duration had been seven weeks. There was some resistance in the right iliac fossa and a tentative diagnosis of intestinal obstruction due to cancer of the cæcum was made. It was resolved to open the abdomen in the right iliac fossa, and when this was done there was found a piece of small intestine with greatly thickened wall, and in the interior there was a hard mass evidently consisting of gall-stones. The mass was firmly wedged in the bowel, but by a little coaxing the stones were pushed upwards into the thickened part of the intestine and were easily removed through a longitudinal incision. The mass consisted of two large gall-stones. The edges of the wound were stitched together and covered in with a row of Lembert's sutures of fine silk. The patient soon improved and at the end of a week the wound was healed, though a small localised collection of pus formed a few days later. Gall-stones are a rare cause of intestinal obstruction, though by now many cases have been put on record.

Mr. E. A. WRIGHT has reported a case of intestinal obstruction due to hair. The patient, a girl aged 21 years, complained of abdominal pain and vomiting, and she stated that the bowels had not acted for several days. On examination a round, hard lump was found in the right epigastric region about the size of an orange, and per rectum a hard moveable mass could be felt. She said she had suffered from constipation for some years. As no marked improvement occurred, though the vomiting was temporarily arrested, the abdomen was opened and the lump was explored by the hand. It was about 3 inches in length, and it was found to block the small intestine completely. The bowel was opened by a small incision and the obstructing mass was removed; the other lump was found to be in the stomach, and by incision in the anterior wall the mass was removed with some difficulty. It was found to consist of a mass of matted hair weighing nearly 3 pounds. Temporary improvement followed, but soon severe diarrhœa occurred and the patient died from exhaustion six days after the operation. Masses of hair in the stomach are rare, and more rarely still is intestinal obstruction produced by a mass of hair.

The Functions of the Omentum.

Dr. D. P. DALBRECK WILKIE has investigated the functions and surgical uses of the omentum. He has proved that it possesses a very remarkable capacity for taking up any solid particles left in the peritoneal cavity, and therefore in acute peritonitis the bacteria tend to adhere to the omentum, which forms a very favourable battle-ground for the phagocytes in the fight between the host and the germs. There is no evidence that the omentum has any power of intelligent movement, and experiments give some ground for believing that in cases of strangulation of the bowel, where the vitality of a portion of it is endangered and a resection of the doubtful part is deemed inadvisable on account of the general condition of the patient, the omentum may with benefit be wrapped round the loop of gut.

Excision of Bowel for Tuberculosis.

Mr. ARTHUR E. BARKER has recorded two cases of extensive excision of the colon and ileum for tuberculous disease, and has described very fully the principles and details of the operation. So much depends on special points in the technique that such a description is of great value. In the first case the patient was a woman aged 40 years, and she had suffered from a fæcal fistula in the right groin for a year. The cæcum, with 4 inches of colon and 27 inches of the ileum, were removed, and the operation lasted two and a half hours, spinal analgesia being employed. The patient recovered completely, and three years after the operation she was plump and well. In the second case a soldier, aged 32, had suffered from signs of chronic intermittent obstruction and wasting. A large tuberculous mass of bowel was removed in two operations; the wounds healed without a flaw and the patient was perfectly well when last seen.

Evagination of Meckel's Diverticulum.

Mr. J. W. THOMSON has described a case of evagination of Meckel's diverticulum. The patient was a baby, 13 months old, with a history that after separation of the cord an opening was noticed at the umbilicus, from which occasionally fæcal matter was passed. After straining much eversion occurred with persistent vomiting. As reduction was out of the question a circular incision was made round the opening and the abdomen was opened. It was found that the fistula was due to a Meckel's diverticulum. The everted diverticulum and the adjoining portion of the intestine were excised and an end-to-end anastomosis was performed. The child seemed to improve for a time but died suddenly ten hours afterwards in convulsions.

Iodine in the Preparation of the Skin for Operation.

Within the last few years iodine as an antiseptic for preparing the skin of the patient for operation has been widely employed, and sufficient time has now elapsed to enable those who have employed it to express a decided opinion as to its value. Its modern use commenced in Germany, and it was first advocated in this country by Mr. J. LIONEL STRETTON, and its use has been advocated by many other writers. The strength employed varies, some using it even as strong as 10 per cent., but this seems unnecessarily strong, and a strength of that of the tincture of the British Pharmacopœia—that is to say, 2½ per cent.—gives very satisfactory results. It is applied by most surgeons a few hours before the operation, and again on the operating table, but in emergency cases a single application suffices.

Section of the Posterior Roots of the Spinal Nerves.

Professor FÖRSTER, of Breslau, who has done much work on spinal surgery, and Mr. E. W. HEY GROVES have contributed papers on the value of dividing the posterior nerve root in certain conditions. Some of the earlier operations were performed for the relief of intense pain, but in only a small minority was the operation successful in its results, and the explanation given by Mr. GROVES is that in the unsuccessful cases the pain was psychical in origin, and therefore it is clear that division of the sensory roots could not do much good. Greater success, however, has been obtained in the treatment of the crises of locomotor ataxia, and in some cases the improvement has been so great that the patient has been able to return to his occupation. The suggestion of this method of treatment came from Professor

FÖRSTER, and he performed the first operation in 1908; also in certain cases of spastic paralysis associated with disease of the pyramidal tract division of the posterior nerve roots has been employed, and with remarkable success in suitable instances. Explanation of this benefit is not clear; at all events, spasm is in all these cases definitely relieved, and if the pyramidal tract is still fairly undamaged great improvement in motility follows.

Cleft Palate.

For several years there has been much discussion as to which operation for cleft palate is to be preferred. The majority of surgeons employ Langenbeck's operation or some modification of it; while a few, headed by Mr. ARBUTHNOT LANE, are in favour of employing the "flap method." In the Surgical Section of the Royal Society of Medicine a special debate was held on the subject, and it was also discussed in the surgical section of the annual meeting of the British Medical Association in Birmingham. The two methods must be judged by their results, age and other factors being duly considered. Sufficient material for a verdict must now be accumulating. Mr. R. W. MURRAY has contributed a valuable paper in which he has detailed the history of the operation and described fully its technique.

Quinine for the Prevention of Pain after Amputation.

Dr. V. PLETH and Dr. V. W. PLETH have described the use of quinine after amputations. A ½ per cent. solution of the bi-sulphate of quinine is employed, and when the amputation is completed, the solution is injected into and round the main nerves, and some is also injected into the tissues covering the stump. No post-operative pain is felt. The solution is non-toxic, it can easily be sterilised by boiling, it is inexpensive, and no harm seems to follow its use.

Operation for Stone in Male Bladder.

Mr. WILLIAM F. HASLAM, of Birmingham, delivered the Lettsomian lectures before the Medical Society of London on the operation for stone in the bladder of the male, and in these lectures he gave an historical account, which we believe has never been surpassed, of operations for stone from the earliest times to the present. He also described and analysed the answers he had obtained to a series of questions which he had sent to surgeons attached to the larger hospitals as to the methods employed by them, and from these answers he was able to deduce several interesting conclusions as to the present practice. It may be mentioned that for the removal of a stone from the male bladder after puberty, when there is no evidence of prostatic enlargement, the majority of the surgeons preferred suprapubic lithotomy to lithotrity.

Transperitoneal Cystotomy.

Mr. SETON PRINGLE has described an important case in which he removed a large papilloma from the bladder of a man 40 years old. He did it through the peritoneum and the result was very satisfactory. The operation of transperitoneal cystotomy was apparently first performed by HARRINGTON in 1893 and he was followed by RICHARDSON in 1895. The mortality appears to be only a little over 4 per cent. and it seems to be indubitable that the operation gives much better access to the growth than the extraperitoneal method, and it is probable that the risk of recurrence is greatly reduced, though as to this it is as yet somewhat early to speak. Mr. PRINGLE has described the mode of operation and has discussed the comparative merits of the ordinary extraperitoneal operation and the newer procedure.

Torsion of the Testis.

Cases of torsion of the testis are not very common. Dr. WILFRED ATTLEE has recorded a case which occurred in a boy, aged 16½ years, who felt pain in the right testis as he was kicking a football. The pain steadily increased and before long he felt faint and vomited twice. He was seen three hours after the first injury and it was readily recognised that the testis had become twisted, and from the history of the case Dr. ATTLEE was inclined to think that the rotation was in the direction of the hands of a clock if one looked upwards towards the patient's head. Manipulation proved this to be correct, for after turning the testis back to the extent of a right angle the epididymis rotated with a jerk back to its normal position and the pain immediately disappeared. It is not always possible to reduce so easily a testis which has undergone torsion of the cord.

Ureteral Grafts.

Dr. A. CHIASSERINI, of Rome, has contributed an interesting article on ureteral grafts, and he describes some of the many experiments he has been making to discover the best material for forming grafts. He has employed pieces of vein and artery to replace portions of the ureter removed, and he came to the conclusion that there was a possibility of the vessel introduced between the two utereral ends becoming firmly united, but the transplanted piece tends to contract so as to draw the two ureteral ends together, and the lumen of the graft becomes nearly obliterated, therefore he is compelled to think that vascular grafts are unsuited for replacing portions of the ureter.

Direct Gastroscopy.

Several recent improvements have been made in the direct gastroscope, and there seems little doubt that by the use of a direct vision gastroscope passed under visual observation there is the minimum risk of doing any harm. Dr. G. WILLIAM HILL gave at the Birmingham meeting of the British Medical Association an interesting demonstration of the use of a gastroscope which he had devised.

Myositis Ossificans Traumatica.

Mr. RICKMAN J. GODLEE and Mr. G. H. MAKINS have each contributed an interesting paper on traumatic ossifying myositis. In Mr. GODLEE'S paper he describes a case in which a youth, aged 18 years, was kicked on the front of the thigh at football. Swelling occurred and kept him in bed for one day. A hard oval enlargement formed on the front of the lower half of the thigh, and two months after the accident he had to give up football on account of pain and stiffness. A skiagram taken a little later showed a definite shadow. It was resolved, in consultation with the late Mr. H. H. CLUTTON, not to perform any operation, and in six months the patient had no further trouble, though still the skiagram showed a small flake of bone. Mr. MAKINS described three cases, in one of which the late Mr. CLUTTON removed a bony mass, but in the other two no operation was performed. They all did well. It seems clear that operative treatment should only be considered advisable when the process has manifestly come to a definite standstill and yet the patient suffers from functional disability.

The Treatment of Syphilis.

A large number of contributions have been made during the year on the subject of the treatment of syphilis, especially bearing on the question of the use of salvarsan. It is obvious that different opinions exist as to the merits of this drug, and more prolonged experience is needed before authoritative statements can be made as to its real range of value and its different methods of administration.

Lymphangioplasty.

The operation of lymphangioplasty is still in its infancy, and surgical opinion has not been yet fully formed with regard to it. Therefore it is desirable that cases of the operation should be published whether successful or not. Mr. R. ATKINSON STONEY and Dr. T. GILMAN MOORHEAD have reported an interesting case in which Sampson Handley's operation of lymphangioplasty was employed for ascites, with disappearance of the fluid. The patient was a man, 20 years old, who was without history of any previous

illness beyond an attack of measles in childhood. The present illness commenced six months previous to admission, and began with pain in the chest and abdomen following exposure to severe cold. Three weeks before admission the abdominal swelling was first noticed. There was much free fluid in the abdomen and a diagnosis of cirrhosis of the liver was made. 175 ounces of serous fluid were removed by tapping. The abdomen, however, soon filled again, but just as it was decided to tap once more the fluid began to disappear and the patient returned home. As the fluid quickly re-accumulated he was re-admitted three months later, and the abdomen was tapped on many occasions, but the fluid always reappeared. It was resolved therefore to operate, and silk stitches were placed in the left iliac fossa from above the crest of the ilium to below Poupart's ligament, four or five stitches being made, alternately in and outside the peritoneal cavity. Similar threads were placed in the anterior abdominal wall. There was no rise of temperature after the operation and the patient did well. After the operation some ascitic fluid collected, but more slowly than before; still there was sufficient to warrant the abdomen being tapped once six weeks after the operation. The patient was able to return home and to take part in the ordinary work of the farm, and there was practically no fluid in the abdomen, but he suffered somewhat from shortness of breath.

OBSTETRICS AND GYNÆCOLOGY.

The Follicle Cells in the Ovary.

There is still, although a large amount of work has been done upon this subject, a good deal of divergence of opinion upon the origin of the follicle cells of the ovary or the stratum granulosum. During the past year Dr. A. LOUISE MCILROY has published the results of her researches on this point, and she has shown pretty conclusively that the follicle cells are derived from the primordial germ cells or the oögonia, and have a similar origin to that of the ova. The oögonia form two divisions according to their ultimate functions; the cells of one group go through a complicated process of maturation, ultimately becoming oöcytes or ova within a Graafian follicle. The other group of cells fulfil three functions; one set remain as reserve cells, serving as pabulum for the growing oöcytes, the second set developing further surround the oöcytes and form the stratum granulosum. The remaining cells go to form, according to Miss MCILROY, the interstitial cells of the ovary, which are concerned with its internal secretion. The follicle cells therefore are derived from the oögonia and not from the stroma.

The Uterine Mucosa in Menstruation and Pregnancy: the Action of the Chorionic Cells and the Function of the Decidua.

The changes which occur in the mucous membrane of the uterus both during menstruation and pregnancy are now well known. In the pre-menstrual phase the mucosa is thickened, chiefly by a free œdematous escape into the stroma, with some escape of blood in the proximity of the vessels. This change is usually described as dependent upon congestion and increased intra-vascular pressure. At the June meeting of the Obstetrical and Gynæcological Section of the Royal Society of Medicine Dr. JAMES YOUNG gave a very interesting demonstration of these changes and of what he considered their correct explanation. He maintains that the changes seen in the pre-menstrual mucosa are amenable to only one explanation—namely, that there has been a widespread imbibition of fluid from the blood-vessels in response to some change in the stroma. He believes that this change is to be found in some alteration in the tissue colloids of the stroma as a result of the stimulus of the substance (probably ovarian) which is responsible for the menstrual changes. He further holds that the escape of the blood occurs in the same way as that of the œdema fluid, and that the whole mucosa may be regarded as a potential blood sponge. He maintains that in cases of tubal pregnancy examination of the tubal wall shows that there are occurring protoplasmic changes which lead to an increase in the affinity for fluid of the tissues. These changes explain the widespread œdema and the escape of the blood rather than any direct erosion and destruction of the vessel walls. Changes of the same kind, he believes, explain the marked formation of sinuses in the wall of the pregnant tube, while the same changes can be demonstrated on a study of cases of chorion epithelioma. The ultimate cause of these changes is to be found in the elaboration by the chorionic tissues of some bio-chemical elements, which spread into further and further levels of the maternal tissues. In fact, except in the decidually altered mucosa there is no attempt at any localisation of these changes. In these considerations Dr. YOUNG sees an explanation of the decidua. Were it not for the decidual reaction the uterine mucosa would in response to the ever-widening spread of the extra chorionic influence be torn up by the œdema, blood, and increasing sinuses. Once the decidual change is definitely established these changes are localised and inhibited. The theory is an ingenious one and worthy of careful consideration. He has set out his views fully in his work on Reproduction recently reviewed in these columns.[1]

The Theory of Enzygotic (Mono-chorionic) Twins.

Before the Edinburgh Obstetrical Society, Dr. D. BERRY HART read an interesting paper upon this obscure subject. By enzygotic twins were understood twins developed from one zygote (fertilised ovum). The most striking instance of these was identical twins, where the similarity was complete, even to the finger-prints (Wilder). It was further noteworthy that all twins derived from one zygote were of the same sex. In considering the causation Dr. HART advanced the theory that one must go back to the zygote itself, and looking on it as containing the determinants for the organs of the developed infant he suggested that in enzygotic twins there might be a complete or incomplete doubling of the determinants, and then a complete segregation of these into two groups. In identical twins the doubling and segregation were complete; in the other deformities the doubling was incomplete, and segregation thus gave a complete twin and an incomplete one. Thus if an acephalic twin was present along with a normally developed one the determinants for the head were not doubled, and thus the acephalic result on one side.

The Nature of Hæmatocolpos Fluid.

A very interesting contribution to our knowledge of this matter was made during the past year by Dr. W. BLAIR BELL. In an examination of the fluid from two cases of hæmatocolpos he found that neither fibrin ferment nor fibrinogen was to be detected, and he concludes that this is the cause of the non-coagulability of menstrual blood, which will clot readily if normal blood be added to it. A considerable quantity of lactic acid was present although the fluid was sterile and the vaginal bacillus could not be found. The actual mode of origin of the lactic acid is therefore still unknown, although it is probably derived from the decomposition of mucin by enzymes without the intervention of bacteria. The chemical examination of this fluid also corroborated Dr. BLAIR BELL'S views as to the amount of calcium contained in the uterine excretion during menstruation. The paper was published in THE LANCET.[2]

[1] THE LANCET, Dec. 16th, 1911, p. 1706.
[2] THE LANCET, May 13th, 1911, p. 1269.

The Modern Treatment of Contracted Pelves.

The important question as to the position in obstetric medicine which operations for widening the pelvis will ultimately hold is still under discussion, and it cannot be said that during the past year much progress has been made in this direction. The operation of pubiotomy meets with scant approval in this country although various obstetricians still continue to practise it in a certain limited class of case, and it has an enthusiastic supporter in Dr. E. HASTINGS TWEEDY. At a meeting of the Obstetrical Section of the Royal Academy of Medicine in Ireland he showed six cases of pubiotomy with skiagrams of the pelves. He had performed the operation in nine cases; all the patients walked without limping or discomfort, and all had made uneventful recoveries. Dr. TWEEDY said that the operation was not only successful but it was the easiest operation one could perform, and any well-informed modern general practitioner who could attend a midwifery case in a proper manner was competent to perform it. The trouble that followed it in other cases was due, not to the pubiotomy, but to tearing of the cervix or vagina. No doubt in a certain small class of cases the operation is easy and successful, but when we recall the complications and difficulties which may attend it, we hope that general practitioners, unless their opportunities for obstetric practice have been distinctly special, will not be tempted by the success attending Dr. TWEEDY'S practice to perform this operation in unsuitable surroundings. The question of the modern treatment of cases of labour in contracted pelves was also discussed by Sir HALLIDAY CROOM before the Edinburgh Obstetrical Society. He pointed out that with the the disappearance of puerperal septicæmia in lying-in hospitals confidence in the powers of nature had returned, and labour in a narrow pelvis was allowed now to complete itself spontaneously in a large proportion of the cases. This method of delivery was very successful for the mother and the child. He thought the great difficulty of treatment lay in pelves with a conjugate diameter between 3 and 3¼ inches. In these cases the choice was between the induction of premature labour, high forceps, and one of the operations for enlarging the pelvis. The first was unfortunately accompanied by a very considerable infantile mortality. In high forceps operations in narrow pelves the mortality and morbidity to the mothers were considerable, and the fœtal mortality was between 20 and 40 per cent. The cases in which operations for enlarging the pelvis were useful were those of moderate contraction of the pelvis in which, after ample time had been given to the head to enter the brim, it still remained unengaged. He thought that no high forceps operation should be seriously undertaken unless the operator was prepared to undertake one of these cutting operations if necessary.

Asphyxia Neonatorum.

At the British Medical Association meeting at Birmingham the important question of the Pathology and Treatment of Asphyxia Neonatorum was discussed, the debate being opened by Sir FRANCIS CHAMPNEYS. He recognised two stages of asphyxia—viz., (1) apoplectic, where the child is livid, the muscular tone is not lost, and it responds to reflex stimulation; and (2) syncopal, where the child is pale and flabby, muscular tone is lost, and there is no response to any reflex. These latter are the serious cases and may be due to pressure upon the brain. With regard to treatment, Sir FRANCIS CHAMPNEYS emphasised the important difference that exists between "blue" and "white" asphyxia. He discussed the subject under the following headings: (1) The removal of all foreign bodies from the respiratory tract; (2) means to secure the patency of the air-passages; (3) stimulation of the circulation; and (4) means to procure thorough ventilation of the lungs. To effect the first object he recommended that the child should be placed on its back, the head extended, and the trachea gently stroked upwards, a finger being placed at the orifice of the trachea. Patency of the air-passages may be secured by the passage of a catheter. The circulation may be stimulated by pressure over the præcordium. The importance of friction over the spine was also emphasised. Ventilation of the lungs might be procured by the time-honoured methods of Silvester or Schultze. The speaker asked the members to note that the normal position of rest in the child's thorax was one of expiration. Schultze's method had the disadvantage of possibly causing internal lesions, but it certainly might procure patency of the air-passages when other methods failed. Furthermore, it procured descent of the diaphragm as in normal respiration. The method should be carried out properly if at all, and Sir FRANCIS CHAMPNEYS insisted upon the importance of simply steadying the child's body and *not* grasping it. Of other methods, reference was made to insufflation and rhythmic tongue traction. In conclusion, the speaker urged his hearers: (1) Never to hurry; (2) to employ sound judgment as to whether the case is one of pale asphyxia or true death; and (3) to persist in treatment over a sufficient length of time. In the discussion which followed the majority of the speakers were not in favour of Schultze's method.

Operative Treatment of Cancer of the Cervix Uteri.

The removal of the uterus in such cases by the extended abdominal operation or Wertheim's hysterectomy has undoubtedly made great progress during the last 12 months, and gynæcologists are becoming more and more convinced that all cases of cancer of the cervix, whether early or late, should be treated by an extended operation if good results are to be obtained as regards freedom from recurrence. It is true that some authorities still maintain that such an extensive removal can be carried out equally well and more safely by the vagina, but they are few in number and are not, we think, likely to gain more adherents in the future. Dr. ARCHIBALD LEITCH has published recently the results of some researches on the Pathological Bases of Operations for Cancer of the Uterus, and his work certainly tends to confirm the position taken up by those surgeons who maintain that the extended operation should be performed in all cases and preferably by the abdomen. He pointed out that statistics had shown that 55 per cent. of cases were free from visceral or glandular metastases at the time of death, but these figures only applied to dissemination outside the pelvic cavity. Three lymphatic tracts were described: (1) to the inter-iliac glands; (2) to glands along branches of the internal iliac artery; and (3) to para-rectal glands. The last set were very rarely affected, in spite of the supposed frequency of invasion of the utero-sacral ligaments. The inter-iliac glands were the most important, and were in communication with another set on the outside of the common iliac artery. Both sets should be removed when there was evidence of glandular infection Along the course of the ureter, through the broad ligament, lymphatic infection of the cellular tissue occurred, and by fibrotic contraction, as well as by direct invasion of its walls, the ureter became constricted, and hydronephrosis ensued in no less than 75 per cent. of all cases. Invasion of the vagina by cancer of the cervix occurred in all but 2·5 per cent. of cases; this was explained by the rich anastomosis of lymphatics between the cervix and upper segment of the vagina. Thus the excision of a wide cuff of vagina in Wertheim's operation removed a highly dangerous tissue. The bladder was involved in two-thirds of post-mortem cases, and the rectum in one-quarter of the cases; while vesical perforation occurred in 44 per cent., and rectal perforation in 16 per cent. of cases.

One of the most important publications during the past year has been WERTHEIM'S results in his first 500 cases operated upon for cancer of the cervix uteri. The 500 cases which form the subject of the report correspond to 1096 cases of cancer seen; of these in 519 the disease was too advanced to be operated upon, 55 refused operation, and in 22 vaginal hysterectomy was performed on account of excessive fatness or age, giving an operability rate of 50 per cent. The average mortality rate was 18·6 per cent., varying from 30 per cent. in the first hundred to 9 per cent. in the fourth. In 250 of the cases five years or more have elapsed since the operation, and of these 63 died from the operation, in 78 recurrence has occurred, and 106 are free from recurrence. In determining the absolute percentage of cures among the 250 cases, 3 who died from intercurrent disease and 28 who refused the operation are deducted, leaving 576 patients, of whom 106 are alive and well at the end of five years, or an absolute percentage of cures of 18·4 per cent. and a percentage of cure of those operated upon of 42·9 per cent. In conclusion, WERTHEIM argues very strongly in favour of the extended operation, although he points out that STAUDE has had very excellent results by the vaginal operation—namely, an operation-rate of 72·3 per cent. and an absolute cure-rate of 23 per cent. It is very probable that the immediate death-rate from shock may be considerably lessened by the more extended use of infusion anæsthesia, a method which answers exceedingly well in these women, who are often much debilitated by loss of blood.

The Dangers of Fibroid Tumours

The actual danger entailed to the life of a patient by the possession of a fibroid tumour of the uterus is one of the problems in gynæcology which is yet waiting a solution. That small fibroids can be removed with a minimal amount of risk is now a proved fact, but before we can lay down the dictum that all fibroids should therefore be removed when still small, it is necessary to prove that the risk to any woman the possessor of a fibroid tumour is, or will be in the future, greater than the 1 or 2 per cent. which at present represents the mortality of hysterectomy under the best conditions. It is, of course, an easy matter to collect a certain number of cases of death directly due to the presence of such a tumour, but what proportion these deaths bear to the total number of women who suffer from fibromyomata of the uterus, and how many of these who are at present operated upon to escape future trouble would ever suffer any inconvenience at all, is a question to which no certain answer has as yet been given. The problem is one which can only be answered by the careful collection of a number of cases observed over a sufficient length of time, and the results must be calculated by approved mathematical methods, when such a series of figures is available, before a certain and correct conclusion can be come to. It is, of course, an undoubted fact that a certain percentage of these tumours undoubtedly do cause dangerous symptoms, and may even cause the death of the patient. During the past year Dr. A. H. N. LEWERS has published the notes of three such cases in our columns. In the first of these cases the patient died from hæmorrhage, in the second from pulmonary embolism, and in the third from sudden collapse and heart failure. It would have been interesting if Dr. LEWERS had been able to state whether these were the only spontaneous deaths from fibroid tumours of the uterus which had come under his cognisance, and what numerical relation they bore to the total number of cases of fibroids he had seen. It is only by the accumulation of figures of this kind that we shall ever learn the truth. Unfortunately, or fortunately as it possibly may be for the patients, it is so general a custom at the present time to remove all fibroids which have attained any large size that there will be but little opportunity of determining the truth as regards this question in the future, since the number of patients with fibroids who will be allowed to attain any advanced age without some one having operated upon them will be very small. In the meantime the habit of stating that such tumours relatively frequently produce severe symptoms, without the production of any trustworthy statistical evidence in support of such statements, is much to be deprecated, and will certainly not aid us in our endeavour to attain a more complete knowledge of this subject.

The Suprapubic Transverse Fascial Incision in Gynæcology.

This incision formed the subject of a paper by Dr. THOMAS WILSON, published in THE LANCET of May 6th of this year. He has used it in some 120 operations on the pelvic organs, and is impressed with its advantages. The method advocated by PFANNENTSTIEL is employed—namely, the division of the skin and fascia of the recti muscles transversely, and after the recti have been pulled apart the division of the transversalis fascia and peritoneum vertically. The general direction of the fibres of the fascia forming the anterior layer of the sheath of the recti is transverse, and this incision therefore really divides these fibres longitudinally, while the usual median or extra median incision divides them transversely. The incision heals well, and the occurrence of hernia is very rare. In 198 cases PFANNENSTIEL found only one case of hernia, while KROENIG in 127 cases observed four cases of hernia—3·1 per cent.—two of them occurring after the wound had healed by first intention. The lessened risk of hernia appears to be the most certain benefit to the patient from the use of this incision, while it affords, according to Dr. WILSON, easier access and more ample room than the longitudinal incision, and finally the cosmetic effect may be of some value, the scar being less perceptible.

The Present Position of Vaginal Operations in Relation to the Uterus and its Adnexa.

Professor PAUL STRASSMANN opened a discussion upon this subject at the British Medical Association meeting at Birmingham. He thought that abdominal section for disease of the pelvic viscera had certain well-defined disadvantages; thus peritonitis was more frequent than after a vaginal operation, and was promoted by the interference with the intestines and to some extent by the Trendelenburg position. A further argument against it was the risk of hernia. Fibromyomata should only be removed by the abdominal route when they were the size of the head of a fœtus. Carcinoma of the cervix should in general be treated by the abdomen, but carcinoma corporis uteri by the vagina. In all cases where appendicitis was suspected as a complication laparotomy should be selected. The advantages which the vaginal route afforded were less shock and a smaller mortality, convalescence was more rapid, and after-effects due to adhesions or hernia were avoided. The disadvantages which had been urged against it were lack of sufficient room, the danger of injuries to the bladder and ureters, the failure of primary union in the vaginal cicatrix, and the production of a weak scar and possibly hernia. Professor STRASSMANN thought that early tubal gestations, hæmatoceles, inflammatory exudates, and displacements of the uterus were best treated by the vaginal route. A very full discussion followed the reading of this paper, and the general opinion among those who took part in it was that, except in well-defined cases, abdominal section was, on the whole, the operation most likely to be required, as in most instances offering the greatest benefit to the patient.

OPHTHALMOLOGY.

This year is distinguished from all previous years in that the Nobel Prize for Medicine has been awarded to an ophthalmologist. We cannot number the prize-winner amongst our own compatriots, but we can none the less whole-heartedly approve of the selection which has been made. Dr. GULLSTRAND, of Upsala, is known to ophthalmologists all over the world for his excellent work on the physiological optics and the applied optics of ophthalmology. In the former branch his recent revision, in conjunction with the late Dr. NAGEL and Dr. VON KRIES, of HELMHOLTZ'S treatise on "Physiological Optics" has brought his attainments prominently into the foreground. In the latter, perhaps, his most noteworthy achievement is to be found in the lenses which have been constructed under his supervision at Jena for cataract glasses. These will probably in time become cheaper to construct, and are likely to replace the ordinary heavy lenses which aphakic patients are at present doomed to wear. The award of the prize to one who has made his reputation chiefly by his devotion to optical problems should do much to encourage the study of an aspect of ophthalmology which is unfortunately much neglected in this country.

Publications.

The most noteworthy addition to the ophthalmic surgeon's library during the past year is Dr. J. E. WEEKS'S treatise on "Diseases of the Eye." Of the "International System of Ophthalmic Practice" two volumes have been published, one on therapeutics, already reviewed in our columns, and one on pathology, by Mr. E. TREACHER COLLINS and Mr. M. S. MAYOU. These volumes show a high standard of aim and attainment, and fill gaps in the literature of the subject. Professor RÖMER'S systematic lectures are also worthy of special mention, though for the most part adapted only to the requirements of advanced students, and then only to such as are familiar with German. The periodical literature of ophthalmology, maintaining its high average standard, contains a vast amount of valuable material, of which some of the more important topics may be suitably discussed with greater detail.

Cataract.

The interest awakened in the advocacy of the intracapsular method of cataract extraction by Lieutenant-Colonel HENRY SMITH, of Amritsar (late of Jullundur), shows no signs of abatement. In England a discussion at the meeting of the British Medical Association at Birmingham exemplified the warmth of the advocacy that is forthcoming in the remarks of Lieutenant-Colonel SMITH himself and of his pupils, Captain A. E. J. LISTER and Miss AMY SHEPPARD, and also, it must be admitted, the coolness of its reception. Ophthalmic surgeons in England are conservative in their methods, and perhaps Lieutenant-Colonel SMITH and his pupils do not sufficiently realise the difference in the conditions which obtain here as compared with India. Suffice it to say that few, if any, English surgeons have adopted the method. It has been viewed more favourably in America, where Dr. GREEN and Dr. VAIL, both of whom have worked under Lieutenant-Colonel SMITH'S supervision at Jullundur, have been the pioneers. The majority of American phthalmologists have not, however, been convinced, and in India itself the operation appears to have gained few adherents beyond the immediate sphere of Lieutenant-Colonel SMITH'S influence.

Glaucoma.

The debt which ophthalmology owes to Anglo-Indian surgeons has been greatly increased during the past year or two by the persevering efforts of Lieutenant-Colonel H. HERBERT and Major R. H. ELLIOT to devise a satisfactory operation for the relief of chronic glaucoma. Iridectomy, introduced by VON GRAEFE on what have since been shown to be inaccurate data, has proved remarkably successful in acute glaucoma The use of new and almost untried methods for this purpose as reported recently, is therefore to be deprecated. It is quite otherwise with regard to chronic glaucoma. To say the least, iridectomy often fails to relieve increased tension permanently in these cases. An effectual operation is urgently needed. Lieutenant-Colonel HERBERT'S early attempts to obtain a cystoid cicatrix were inherently objectionable on surgical grounds and proved too uncertain to be of value. His "wedge" operation had technical difficulties which prevented its general employment, and it is doubtful if it would have succeeded in other hands in bringing about the desired result. Meanwhile HEINE'S cyclodialysis was brought forward, but it, too, has not fulfilled the hope with which it was greeted. Reunion between the ciliary body and sclerotic occurs and frustrates the object of the operation. Combined with trephining of the sclerotic, it has been advocated by Dr. A. FREELAND FERGUS. For a considerable time Dr. LAGRANGE'S modification of ordinary glaucoma iridectomy, consisting of the excision of a small portion of the anterior lip of the scleral wound, held the field as the most satisfactory method of obtaining a filtering cicatrix—the object which all these operations with the exception of cyclodialysis aim at. Lieutenant-Colonel HERBERT, however, continued in England the researches commenced in Bombay. His small flap sclerotomy bids fair to meet the requirements of the case. During the past year a number of English surgeons have published the results of their experience of the method, and on the whole they have been favourable. The technique of the operation has been simplified by the use of "twin" scissors, devised by Mr. N. BISHOP HARMAN, but Lieutenant-Colonel HERBERT states that his results have not been so satisfactory when this instrument has been used. Time alone can show what modifications in technique may be desirable, but the operation has already proved that it merits extended trial. It appears to be little known yet on the continent and in America.

Major ELLIOT'S trephining operation is designed to meet the same requirement—the establishment of a permanently filtering cicatrix. He reflects a large flap of conjunctiva, burrowing somewhat into the cornea at the limbus. A disc of sclerotic is then removed so that an opening is made into the anterior chamber near the angle. The opening is then covered by the conjunctival flap. Those who have employed this method have been favourably impressed by the results.

HERBERT'S and ELLIOT'S operations go a very long way to prove the efficacy of a filtering cicatrix for the relief of chronic glaucoma. Whether either ultimately proves the ideal method of bringing about the desired result or not, the present year is signalised by an important step forward, and the credit of the advance is due to the untiring efforts of British ophthalmologists.

The Treatment of Lacrymal Obstruction.

The revolt against the use of probes and styles in the treatment of severe dacryocystitis and lacrymal obstruction has gathered strength of recent years, and probably the majority of surgeons would now endorse the opinion of FUCHS that a permanent result from probing is one of the rarest exceptions. Extirpation of the lacrymal sac efficiently carried out is generally regarded as an eminently satisfactory procedure, followed by the greatest possible relief of the distressing symptoms. The operation, however, is often performed uncompletely—epiphora persists, even in the absence of unusual stimulation, such as cold winds, foreign bodies in the eye, and so on; and faulty operations of this kind are responsible for that relatively small number of surgeons who advocate other methods. TÖRÖK, of New York, for example,

states that he has "never experienced the cessation of the tearing six or eight months after the operation," and has had to resort to total extirpation of the lacrymal gland. He has never seen satisfactory results either from extirpation of the accessory lacrymal gland or from partial extirpation of the main gland. Dissatisfaction with the results of removal of the lacrymal sac has usually led to attempts at securing permanent drainage into the nose, a reversion to the methods of CELSUS, PAULUS of Ægineta, and SAINT YVES. LAGRANGE, AUBARET, and HESS recommend perforation of the lacrymal bone. Rhinologists have attempted to secure better results by attacking the disease by way of the nose. POLYAK removes the anterior third of the inferior turbinated bone and probes the duct from below. KILLIAN adopts the same procedure, but also removes the whole of the inner wall of the lower part of the duct. The importance of due attention to the condition of the nose and its accessory sinuses is too often overlooked by ophthalmologists, and AXENFELD, an ardent advocate of extirpation of the sac, has done well to bring forward cases in which brilliant results have followed operative treatment by this route in suitable cases. In 1904 TOTI, of Florence, described a new operation—dacryocystorhinostomy—in which the lacrymal bone is resected, an opening is made in the nasal mucous membrane, and the mucous membrane of the sac is brought into continuity with that of the nose. SCHIRMER, ELSCHING, HOLTH, and TÖRÖK warmly advocate this method abroad, and Mr. CHARLES HIGGENS has recently reported a successful case in England. TOTI obtained 23 perfect results and 16 with slight epiphora, SCHIRMER 5 perfect and 3 with epiphora, SALUS in ELSCHING'S clinic 6 perfect, 4 with slight epiphora and 1 with a result equalling an extirpation of the sac, and TÖRÖK 6 perfect, 2 with moderate epiphora, and 1 equal to an extirpation of the sac (no secretion, but lacrymation). The operation is a relatively severe one, involving a large semilunar incision commencing about the junction of the middle and inner third of the upper orbital margin, extending to the side of the nose, round and well in front of the insertion of the tendo oculi, and continued to a point a little beyond the junction of the middle and inner thirds of the lower orbital margin. AXENFELD and WESSELY mention two cases in which Toti's operation failed through gradual closure of the opening in the bone.

Salvarsan ("606") in Eye Disease.

The use of salvarsan ("606") in the treatment of syphilitic diseases of the eye has not been neglected by ophthalmologists, and if the somewhat extravagant hopes raised have not been fully substantiated the drug appears to serve a definitely useful purpose. FLEMING bases a report on 180 cases of syphilis of the eye treated in Professor GREEFF'S clinic in Berlin. He concludes that in "606" we have an effective treatment for syphilitic diseases of the eye in which a rapid result is essential or when cases have failed to respond to mercurial or iodide treatment. STUELP collected 457 cases of ocular disease treated with salvarsan; according to the reports 65 per cent. showed rapid improvement, 35 per cent. showing no change. UHTHOFF found the best and most constant response in cases of acute specific and gummatous iritis; only 11 per cent. of cases of interstitial keratitis showed marked improvement, seldom better than under the usual treatment, and affection of the second eye was not prevented by the drugs; choroido-retinal affections and tabetic optic atrophy were not influenced. BENDA records almost identical results from ELSCHING'S clinic, but no improvement occurred in interstitial keratitis. The disappearance of gummatous nodules of the iris after a single injection is little short of magical, but these cases usually respond rapidly to ordinary antisyphilitic treatment. SCHNAUDIGEL, of Frankfort, records the cure of a tarsitis of several months' duration in two days. English ophthalmologists have been disappointed with the result in cases which have failed to respond to the time-honoured treatment of syphilis with mercury and iodides. The ill-effects attributed to the treatment in some of the earlier cases were due mainly to defects in technique, and are rarely met with when due caution is observed.

Mr. S. H. BROWNING, the bacteriologist at Moorfields Eye Hospital, has found that the blood count in cases of sympathetic ophthalmia shows changes indicative of a protozoal infection. The inference that sympathetic ophthalmia might respond to treatment with "606" has met with encouraging results in practice.

Vaccine and Serum Therapy.

Vaccine and serum therapy continues to be employed with unremitting determination in recalcitrant diseases of the eye. Mr. J. B. LAWFORD, in his recent presidential address before the Ophthalmological Society of the United Kingdom, reviewed the subject in an eminently lucid and judicial manner, lacking only in one feature—a more precise expression of so excellent a clinician's own observations and conclusions. In the absence of definitely expressed opinion, however, the general trend of the argument displayed a subtle modulation from the major to the minor key.

DENTAL SURGERY.

A steady progress in the position of dentistry can be recorded during the past year. This progress is shown, not only in the more scientific character of many of the papers published, but also in the increased attention to the question of dental disease on the part of the general body of medical men as well as the general public.

Dental Disease in Children.

During the year considerable attention has been given to the problem of the treatment of the teeth of school children. In these columns we have advanced the view that the best results would be obtained by organising instruction to the parents on the care of the teeth, and then, if funds permit, adopting remedial measures for the children under six years of age before attempting the treatment of those beyond that age. The reverse method is usually adopted by the educational authorities, with the result that the money allocated to dental treatment is not spent to the best advantage. Accounts of the work accomplished by several of the school clinics have been published. We note that the London authorities have instituted lectures to parents on the hygiene of the teeth, but the treatment of the children still seems to centre around the age-period of six to eight years. The Council has sanctioned the employment of anæsthetists, but this step should have been adopted in the initial stages, for it is quite clear to those acquainted with the treatment of children that the extractions which are so often the rational preliminary to conservative operations can only be efficiently carried out under anæsthetics.

Dental Caries.

Under the title of "The Prevention of Dental Caries" two interesting papers have appeared from the pens of Dr. J. SIM WALLACE[1] and Dr. STANLEY W. R. COLYER.[2] The former author maintains that the "only thoroughly reliable method" of preventing dental caries is the natural or physiological one, and that the solution of the problem is to be found in a dietary which leaves the mouth physiologically clean at the end of the meal. He considers that the dissemination of knowledge necessary for the prevention of dental caries must be mainly made through the medium of the general practitioner of medicine. Dr. COLYER, on his part, considers that the

[1] Dental Record, June 1st, 1911.
[2] Ibid., May 1st, 1911.

prevalence of dental caries is due to food changes, the two most important being (1) the increased amount of soluble fermentable carbohydrate; and (2) the constant introduction into the mouth of acid-fermenting organisms.

Several communications have appeared on the relation of bread to dental caries. Mr. T. G. READ [3] considers that the use of the roller-milled flour is mainly responsible for the large amount of caries seen in the present day, while Dr. WALLACE [4] in a thoughtful paper considers that but little caries can be laid at the door of bread. His conclusions are: (1) That no farinaceous foodstuff in general use is less harmful than bread-and-butter; (2) that the varieties of bread make no appreciable difference in inducing caries, beyond the difference which the physical characters of the bread make in their detergent effects on the teeth; and (3) that crust is a long way preferable to crumb in all varieties.

In reference to the treatment of extensive caries so often seen in children, Mr. J. F. COLYER [5] advocates the removal of all functionless deciduous and permanent teeth. He gives records of children of ages varying from four to ten years who have been left without any masticating area and shows that they improve in health and increase in weight as a result of the removal of the sepsis. He shows, too, that the fear so often expressed, that early removal of the deciduous teeth is extremely harmful to the growth of the jaw and the position of the successional teeth, is unfounded.

Periodontal Disease.

The relationship of suppurative conditions of the periodontal membrane to general disease formed the theme of two interesting papers by Dr. W. KNOWSLEY SIBLEY [6] and Mr. C. GOULDEN.[7] The former author drew attention to the frequent presence of periodontal disease with many forms of skin disease, while the latter author quoted some interesting cases, clearly demonstrating that the focus of infection in many intra-ocular conditions were distinctly traceable to the periodontal membrane. Under the title of "Pyorrhœa Alveolaris: its Interpretation," Mr. HOPEWELL-SMITH,[8] from a consideration of microscopical sections of cases, considers that the course of events are as follows: atrophy of the bony socket and shrinkage, followed by a widening of the gingival margin and broadening and deepening of the pockets around the teeth, with hypoplasia of the periodontal membrane. If a pathogenic infection occurs there is a lodgment of pyogenic bacteria in these already suitable pockets, and pyorrhœa results, but may or may not be accompanied by gingivitis and the production of tartar. The author's conclusions differ considerably from those of others who have written on the morbid anatomy of the disease and from many of those possessing an extensive clinical experience.

Irregularities of the Teeth.

Mr. N. G. BENNETT,[9] in a paper on the Etiology and Classification of Abnormal Development of the Jaw, considers that there is a danger at the present time of under-estimating or entirely neglecting factors of inheritance. He emphasises the importance of regarding deformities of the dental arch as a measure of defective bony growth. He states that it is obviously absurd, in conditions depriving the child of the proper incentive to growth, to think that the alveolar process alone will be affected, and he considers that the abnormal position of the permanent teeth and of the form of the enveloping alveolar process should be regarded as secondary results of inhibited growth of the body of the bone itself. In a paper on the Relationship of Nasal Obstruction to Contracted Arches and Dental Irregularities Mr. ROLLESTON WHITTAKER [10] refers to the very important question of thyroid inadequacy, and suggests that there is a relationship between this and dental conditions.

The Histology of the Teeth.

An important advance in our knowledge of the ultimate termination of the nerves of the pulp has been scored by Mr. J. HOWARD MUMMERY.[11] He has shown that from the nerve plexus under the odontoblasts nerve fibrillæ pass direct into the dentinal tube along with the dentinal fibril. This observation must be regarded as one of the greatest importance in the study of the question of the sensitiveness of the dentine. Mr. MUMMERY'S observations were made on sections which had been treated with iron and tannic acid, the procedure being briefly as follows. Sections are cut and stained with a 2 per cent. solution of perchloride of iron, and then thoroughly washed; they are then treated with a 2 per cent. solution of tannic acid and watched under the microscope until they are sufficiently black.

Prosthetic Dentistry.

In connexion with dental prothesis, a valuable paper has been published by Mr. J. H. BADCOCK,[12] in which he condemns the so-called collar crown and advocates dentures designed in a way to leave the gingival margin free. The paper, which was read before the annual meeting of the British Dental Association, evoked a considerable amount of criticism, some of which was based on an inadequate knowledge of pathological processes in the mouth. Two other papers illustrating the scientific standpoint from which the problem of dental mechanics is being approached have been written, the one by Mr. H. J. MORRIS [13] on the Comparative Elasticity and Internal Structure of Cast and Rolled Gold Plates, and the other by Mr. D. M. SHAW [14] on the Causes of Platinum Fractures in Porcelain Teeth.

Miscellanea.

Amongst communications of interest may be noted a series of articles on dental radiography which have appeared in Items of Interest; a paper by M. H. CRYER [15] on Pathological Changes in the Jaw; and a suggestive article by W. RUSHTON [16] on a Possible Cause of Facial Asymmetry.

Obituary.

Amongst those who have passed away we notice the names of F. EWBANK, H. N. GODDARD, A. F. HARE, T. HEADRIDGE, W. W. CADWALADR JONES, G. A. PEDLEY, W. H. PIDGEON, T. W. THEW, W. WADE, and W. WHITEHOUSE.

New Publications.

"The Royal Dental Hospital of London: Annual Reports" "Modern Dental Materia Medica," third edition, by J. P. BUCKLEY; "Dental Materia Medica, Pharmacology, and Therapeutics," second edition, by C. W. GLASSINGTON; "The American Text-book of Operative Dentistry," fourth edition, edited by E. C. KIRK; "A Manual of Dental Prosthetics," by G. H. WILSON; "Notes on Dental Anatomy," second edition, by T. W. WIDDOWSON; and "Dental Metallurgy," by W. BRUCE HEPBURN. We also have to note the excellent alterations in the *Dental Record*.

ANÆSTHETICS.

An exceptional number of valuable papers have been published during the year dealing with practically new departures in the methods in use. The lessened value attached by many workers to spinal analgesia has stimulated investigation in other directions, resulting in an improved technique in intratracheal etherisation, intravascular infusion, and the use of nitrous oxide with oxygen in major surgery, as well as the wide extension of the employment of alkaloidal bodies to produce a "predomitium."

Intratracheal Ether Insufflation.

Some two years ago Dr. S. J. MELTZER and Dr. AUER published their paper on Continuous Respiration without Respiratory Movements. Since then they have continued their experiments. The former points out[1] that the essentials of the method are (1) the introduction into the trachea to near its bifurcation of a flexible tube the diameter of which is smaller than the lumen of the trachea, and (2) a continuous stream of air driven through this and returning by the side of the tube. This obviates all "dead space" and forces out all vitiated air. This procedure eliminates all the complex problems involved in the normal respiratory mechanism and maintains any desired pressure within the lungs. This method has, at Dr. MELTZER'S suggestion,[2] been adopted for the administration of ether, and with the happiest results. Anæsthesia can be maintained with impunity for hours provided the strength of the ether vapour is adjusted to the requirements of the patient and sufficient, but not excessive, pressure is maintained. The respiration if slowed and rendered shallow indicates excessive etherisation. The use of chloroform vapour by this method appears to be more dangerous. It is at present in an experimental stage.

Dr. C. A. ELSBERG[3] has designed an apparatus for this method, and his experience with it is wholly satisfactory. The patient is anæsthetised by ordinary methods; a catheter is then passed into the trachea, a laryngoscope being used, and is then fixed by a clamp and connected up with the ether supply. His apparatus is more complicated than that of Dr. A. EHRENFRIED,[4] who, in the course of his papers, refers to the pioneer work of TUFFIER, QUÉRIN, VOLHARD, HIRSCH, SOLLMAN, L. ROBINSON, MATAS, BLOOM, PARHAM, SAUERBRUCH, and BRAUER.

Dr. EHRENFRIED'S apparatus consists of a Woolfe's bottle, with three necks, surrounded by a copper water-jacket, and supplied with air by a foot-bellows. A motor can replace the bellows which drives air through the hot water over the ether in the bottle, or actually through the ether if a strong vapour is required. Air can be mixed with ether-vapour of any desired strength and in any proportion. Connected with the delivery tube is a safety valve and pressure-regulator—a bottle of Hg into which a tube is plunged. Any sudden rise of pressure—e.g., such as that caused by laryngeal spasm—will cause the valve to blow off automatically and so safeguard against the risk of interstitial emphysema. The temperature of the air-ether mixture is maintained 10° above that of the room. The air is moistened and filtered before entering the catheter which intubates the trachea. There appear to be no unpleasant after-effects, no hoarseness, laryngeal catarrh, and no excess of mucus. Scopolamine and morphine are used by Dr. EHRENFRIED as a preliminary injection. The method is of the utmost value in thoracic operations, as 20 mm. Hg pressure will maintain a moderate distension of the lungs, even when the thorax has been opened. Aspiration of blood, pus, vomitus, or mucus is, we are assured, completely prevented by the back rush of air which passes by the side of the catheter. The apparatus possesses the advantage of being much more simple than others.

Mr. H. MORRISTON DAVIES,[5] in describing his hyper-atmospheric apparatus, criticises MELTZER'S method adversely, as he considers it defective in that the pressure of the air in the tube is never known with exactitude. His own method involves complete plugging of the larynx. He uses chloroform from a dosimetric inhaler through which the anæsthetic is driven into the lungs. Dr. H. FISCHER,[6] referring to the intratracheal insufflation of ether, emphasises the importance of obtaining an accurate idea of the diameter of the trachea. He states that he can do this by means of callipers at the suprasternal notch. If the space between the tube and the trachea is too great the escape of CO_2 is excessive, so that apnœa occurs, while if the catheter used is too small the lungs cannot be sufficiently expanded. He deprecates the use of a motor to propel the air in, as he regards intermittency in ether supply an advantage.

Intravascular Anæsthetisation.

Although FLOURENS introduced ether into the crural artery of the dog, the method has only recently been revived, probably because C. BERNARD'S experiments led him to pronounce it highly dangerous. JEREMISCH,[7] working in KRAWKOFF'S laboratory, was led to employ hedonal in physiological saline intravenously. As the results were favourable he adopted it for patients in FEDOROFF'S clinic. 1 per cent. hedonal and 5 per cent. urethane in 200 c.c. saline were used. No serious effects followed in 65 cases, although a too rapid introduction led to respiratory difficulty. One case was under operation for 2 hours 52 minutes. Relaxation took place in from 5 to 8 minutes. The injection was made peripherally in order to avoid clotting. The return to consciousness was rapid or delayed according to the quantity of the drugs used. Injection into the saphenous vein necessitated a much larger quantity of the drug, and one case had to be completed under chloroform. PAUL W. HARRISON[8] injected 2 gr. cocaine (2 per cent.) into the vein of his own hand. He found analgesia was slight, but his mental condition was affected and he believes the plan is unsafe.

SCHMITZ-PFEIFFER[9] deals with intravenous injection of ether and is unfavourably disposed towards the use of the method. He admits that BURKHARDT'S cases were favourable, but points out that WITZEL as well as his pupils have been led to regard the proceeding as dangerous. KÜTTNER, after an experience of 23 cases, in which he met with two serious complications—one of pulmonary embolism and one of clotting at the seat of injection—has relinquished the method, since he regards it as too open to peril. SCHMITZ-PFEIFFER claims that his observation of his 40 cases justifies his statement that intravenous diffusion of ether is justifiable only in such cases as are unsuitable for other methods. He prefers the Roth-Dräger inhaler as being safer. He employed as a preliminary the injection of scopolamine and morphine and injected 200 c.c. to 300 c.c. of saline with 5 per cent. ether into the median vein after local infiltration of the tissues. The longest operation took 2 hours 20 minutes. He met with cyanosis, one case of asphyxia, and some thickening and thrombosis at the site of injection. Necropsies made on 11 patients whose death was due to the disease from which they were suffering showed no marked effects resulting from the infusion except occasional thrombosis in the arm. R. HAGEMANN[10] is more favourably impressed by the method,

which he has adopted for head operations as well as for those on the jaws. He points out the advantage of copious injections of saline solutions in cases of extreme debility.

Dr. W. W. BABCOCK[11] reviews the whole subject. He deprecates BURKHARDT'S method with chloroform; it is, he thinks, too dangerous, although still employed by some Russian surgeons. He mentions 100 cases, which included one death and several instances of embolism. Subcutaneous injection of narcotics, such as hyoscine, morphine, apomorphine, except in the cases of young children, appeals to him as safer. Although only 10 per cent. of cases treated in this latter way lost reflex excitability, operative procedure was not impracticable. He associates rectal injections of decinormal saline containing alcohol with the hypodermic injection. The latter is repeated if necessary in 15 minutes. Although not satisfactory for abdominal cases, the plan answers well for mouth and jaw operations, but involves the drawback that as the drugs employed paralyse the emunctories elimination is often unduly delayed. It is therefore essential that the respiration should be watched until the patient is fully conscious.

Mr. F. ROOD[12] gives an encouraging account of his experience of ether given by intravenous infusion, and describes a simple and efficient apparatus which appears to safeguard the patient against some of the dangers of the method. The infusion is continuous, not intermittent, 5 per cent. ether or less is employed, and a warming chamber, as well as an air or ether bubble-trap, is interposed between the supply and the patient.

Professor H. KÜMMEL,[13] following Professor BURKHARDT'S present method, continuous infusion, reports 90 cases; the patients, being feeble, were regarded as unfit for other methods. There was no nausea or vomiting. He points out that the dangers of embolism, thrombosis, and hæmatolysis, although frequent with the intermittent method, have been practically eliminated by continuous infusion. BURKHARDT has met with none in 250 cases, and KÜMMEL'S 90 cases were without incident. He considers KÜTTNER'S case, referred to above, as explicable independently of the method of anæsthesia. KÜMMEL has two supply vessels, one containing ether (5 per cent.) in normal saline solution, and one only normal saline solution, which are connected with the infusion apparatus by a Y-shaped piece. When anæsthesia is induced, and this occurs in from five to ten minutes, usually without any stage of excitement, he runs in saline solution only, supplying more ether when necessary. The amount infused varies in individual cases; one lasting 140 minutes took 1700 c.c. of the solution.

BARTELEMAN'S[14] reference to the dangers of copious intravenous infusion appears germane to this subject. KOENIG had two deaths which he considered were hastened by this cause. The view adopted is that the bactericidal properties of blood are lessened by dilution, and so not only is the method fraught with peril when the heart is feeble, but also when septic peritonitis or other septic serious inflammation exists. Air embolism is dealt with by V. P. BLAIR and H. MCGUIGAN.[15] They suggest as a means of combating the accident the introduction by a fine needle of 2 c.c. of 1 in 1000 solution of adrenal solution in 40 c.c. of normal saline solution into the right ventricle with the view of stimulating it to violent contraction.

Intravenous anæsthesic infusion was discussed at the recent Congress of the German Surgical Association. Professor V. FEDOROFF reported 530 cases in which hedonal (0·75 per cent.) was employed without complication. Professor KÜMMEL reported 100 cases of the use of ether by this method, stating that if adrenal or digalen was added thrombosis resulted. F. M. PIKIN, H. SCHLIMPERT, A. BRÜNING, CLAIRMONT, and W. DEUK, the last two named from experimental evidence, have pronounced against the method. Their experience, however, appears to have been a restricted one. R. VOGELMANN cautions against its employment in patients suffering from advanced degenerations affecting the vascular system.[16]

Rectal Ether Narcosis.

ARND[17] regards the method of introducing into the rectum a 5 per cent. ether solution in normal saline solution as safer than the older method of rectal etherisation by vapour. Anæsthesia appears in five or ten minutes. After the operation is completed all fluid is withdrawn. Diarrhœa without blood or mucus may follow, but does not appear to be of any importance. ARND gives a preliminary hypodermic injection of scopolamorphine.

Nitrous-oxide Gas in Major Operations.

The growing preference for this anæsthetic among American surgeons has called forth a number of useful articles addressed to this subject. Dr. CRILE,[18] an enthusiastic exponent of the method, gives his patients scopolamorphine before the gas, and mixes the latter with oxygen according to the requirements of the case. He has done a large number of major operations in this way, and, as he reminds us, Dr. TETER has recorded some 20,448 inhalations, mostly for cases lasting 15 minutes or less, but including 346 which lasted from 30 to 60 minutes, 228 lasting from 1 to 2 hours, 22 lasting from 2 to 3 hours, and 2 lasting from 3 to 4 hours. CRILE lays great stress upon the avoiding psychic shock, as well as the injury—"insult to tissue"—which, even when the patient is unconscious, acts prejudicially upon the central nervous system. This, he affirms, can be avoided, by gentle handling of the tissues under operation and the avoidance of displacement of, or dragging upon, organs or serous membranes when these possess a complex nerve-supply.

Besides Dr. TETER'S apparatus, one has been designed by Dr. E. I. MCKESSON,[19] who, influenced by Dr. YANDELL HENDERSON'S brilliant research on acapnia, advocates within limitations the advantage of allowing re-breathing and so maintaining the CO_2 content of the blood. Dr. W. D. GATCH[20] advances similar arguments, and points out that an enormous saving of the anæsthetic is thus effected without detriment to the patient. E. D. MARTIN[21] regards the anæsthesia of nitrous oxide *plus* oxygen *plus* carbonic dioxide as less provocative of post-operative shock or other after-effects than is ether. These and many other writers admit that there are drawbacks to this use of nitrous oxide, of which some may be avoided by skilled administration, but others, such as muscular rigidity, cyanosis, and tendency to an irregular grade of anæsthesia, are hardly to be eliminated, even by expert anæsthetists. In this country re-breathing has been discountenanced because unless the expired gas is filtered not only CO_2 is re-introduced but material exhalations from the lungs, and these can hardly be without an appreciably bad effect upon the patients.

That the most serious surgical procedure can be done under N_2O+O_2 is now proved. Dr. F. J. COTTON[22] and Dr. W. M. BOOTHBY report the excision of the rectum done under this mixture of gases introduced by intratracheal insufflation and

[22] Ibid., Nov. 18th, 1911.

with excellent results. A. L. FLEMMING,[23] influenced by CRILE'S strong advocacy of N_2O, has devised a method of alternating nitrous oxide gas and ether. His experience leads him to believe that after some experience an equable anæsthesia can be ensured and immunity from the after-effects associated with ether and the rigidity so inconvenient a symptom of N_2O given by itself. The method is less costly than N_2O and oxygen used continuously.

Scopolamine and Morphine.

J. R. FREELAND and B. A. H. SOLOMONS have employed injections for 100 primaparæ, with only 13 failures.[24] The injections were given only when labour was imminent, and scopolamine but not morphine was, if necessary, repeated. They regard the ritual of GAUSS, the darkened room and so on, as quite unnecessary. In some cases the drugs were given by the mouth and with equal success. They met with no untoward symptoms, but they emphasise, as, indeed, do all those who have used these methods during parturition, that the women require the most sedulous watching. On the other hand, the editor of the *Therapeutic Gazette*, in reviewing the subject, states that experience has shown, so far as surgical procedure is concerned, that this combination is of no use except to produce what Dr. WEIR MITCHELL has felicitously termed the "predomitium," and must be followed by some general anæsthetic.

The value of these alkaloids before general anæsthetics formed the subject of a discussion held at the Royal Society of Medicine, which was opened by Dr. DUDLEY BUXTON. He stated that his experience was satisfactory, and gave his reasons for preferring the addition of atropine (gr. 1/100) to the scopolamorphine injections. This preference is based upon the fact that there is a mutual antagonism and adjuvancy between the drugs in various directions. Mr. ROOD[25] recorded 400 cases in which this plan had proved valuable. Dr. J. S. DARLING[26] adopts the method, but supplements it by doses of trional or sulphonal given over-night.

Mr. DUDLEY CORBETT has advanced arguments from his personal experience to show that the scopolamorphine method is of greatest value in the first stage of labour, especially in the case of hysterical patients. He has seen no bad effects following repeated injections, but points out that asphyxial apnœa may be provoked in some infants, a condition due, he thinks, to the morphine, and is best met by immersion in a hot bath. Strychnine he asserts may be advantageously added to the injection since it does not lessen the analgesia.

A full discussion of the subject of alkaloids employed as adjuvants to general anæsthetics is presented by Dr. DUDLEY BUXTON in a clinical lecture published in the *Clinical Journal* of June 14th. Some writers in America do not accept so favourable a view, and deprecate the use of scopolamorphine since, they contend, it obscures the symptoms which guide the anæsthetist, while it increases the patient's sense of misery and prevents the lungs being cleared by coughing. J. ROBERTSON[27] expresses a favourable opinion of omnopon when given before "open ether."

Omnopon.

Some useful papers have appeared dealing with Dr. SAHLI'S valuable suggestion that the standardised chlorides of the alkaloidal bodies of opium should be employed before general anæsthetics instead of morphine. As is commonly recognised, the chief perils associated with the joint employment of alkaloids and chloroform or ether arise through the uncertain effect of morphine and the variations in the strength of the preparations which are injected. H. M. W. GRAY[28] has employed omnopon largely both with local analgesics and in association with scopolamine. He regards this method as "ideal," for it extends the range of utility of local analgesia, since the patient is practically asleep and so protected from psychic shock. In old patients and in heart and lung diseases he regards the procedure as being free from danger. In renal disease his experience with omnopon is not wide enough to allow of the expression of a definite opinion. Mr. C. L. LEIPOLDT'S report[29] on omnopon gives an interesting and a fairly exhaustive account of the subject as well as his clinical experience, which appears to be quite favourable both as regards the use of omnopon alone and in conjunction with scopolamine.

Spinal Analgesia.

The *Therapeutic Gazette* (June), in reviewing the current views of surgeons concerning the various methods for compassing painless surgery, emphasises that, although some enthusiastic advocates for intradural injection retain their faith in its pre-eminence, yet most of those who have tried it have come to regard it as too dangerous for routine employment. Admitting its value in individual cases they accept ether or nitrous oxide given by modern methods as being safer and more under control. There appears to be reason to believe that in the case of some of the deaths chromatolytic changes were seen in the ganglia throughout the nervous system and degenerative changes in the large polygonal cells of the anterior cornua of the cord. It is stated that similar changes can be produced experimentally with stovaine injected into dogs. Dr. W. F. LORENZ[30] narrates an experience. By the sudden extension of his spine a patient broke the needle during an intradural injection. Failing to find it at the time, the patient was subsequently X rayed and the needle removed *secundum artem* under a general anæsthetic.

Dr. LUSK,[31] besides giving a detailed account of special dissections of the spinal column, has explained the way in which many of the accidents due to the method arise and how some may be avoided. His view is wholly constructive and of great value, both because it is original and because it evinces scientific caution expressed with a judicial fairness. The danger of the method is illustrated by a reported case[32] of an apparently healthy woman who developed meningitis after lumbar puncture. The Wassermann test being applied later, syphilis was discovered and salvarsan administered.

H. E. S. STIVEN[33] records his experience of intrathecal analgesia in Egypt. It has proved satisfactory in his cases. The careful research undertaken by LAWEN and VON GAZA[34] into the effects of extra-dural injection of novocaine can only be mentioned. Their main conclusion is that the rapidity with which fatal results follow depends upon the rapid absorption and high pressure in the extra-dural space. Very slow injection obviated the dangers. Clinical records made at Leipsic confirm this statement. Dr. W. J. MCCARDIE[35] has made a comprehensive collection of the statistics and experiences of continental, of British, and of American surgeons, and he places spinal analgesia among the less safe methods. He gives the mortality as 1 in 826, but HOCHMEIER and KOENIG'S figures record a higher rate of fatality—viz., 1 in 200. Whatever may be the merits of the method for exceptional cases, it seems clear that it cannot be reckoned upon as providing a lessened risk to life. The after-effects, according to most authorities, are of a graver and more persistent type than accrue in the case of

general anæsthetics. Dr. SCHLIMPERT and Dr. SCHNEIDER [36] describe the technique of injection into the sacral canal, which, although difficult in stout persons, is, they consider, valuable in gynæcology and obstetrics. They employed scopolamorphine antecedently.

The increased range of choice, both as regards the agents to be employed and the method of their employment, which has become necessary in order to facilitate the performance of the complicated operations of surgery now carried out, has formed the subject of a paper by Dr. DUDLEY BUXTON in the *British Medical Journal*.

Local Analgesia.

Quinine hydrochloride has been extensively used, especially in America, for local injection. Dr. A. E. COX [37] extols its value. Dr. W. GREEN [38] uses quinine and the hydrochloride of urea, which appear to be not only analgesic but slightly hæmostatic; 1 to 4 per cent. is used. Dr. W. A. BOYD [39] reports a wide experience. He points out that strong solutions of these analgesics cause fibrous induration and retard or prevent union by first intention. HERTZLER finds that a 0·5 per cent. solution will make tissues insensitive for four or five days, while the effect of 1 per cent. may persist for weeks. A 0·25 per cent. solution is usually sufficient and may be boiled, but according to GRAHAM should not be introduced intravenously. The analgesia appears in from 10 to 20 minutes. GAUDIER, of Paris, regards this compound of analgesics as equal in effect to cocaine, while it is free from danger.

A. LAEWEN [40] narrates successful attempts at the performance of extensive operations upon the kidneys with the use of local analgesics. These included pyelotomy and operations for nephrolithiasis. He injects adrenalin and novocaine superficially, and then using various strengths of novocaine seeks for and blocks the first, second, and third lumbar and twelfth intercostal nerves.

Regional analgesia by nerve trunk blocking is one of the great difficulties in local infiltration. Dr. HIRSCHEL [41] contributes useful details of his elaborate technique for infiltrating the brachial plexus for operations upon the arm. He uses 2 per cent. solution of novocaine.

Post-anæsthetic Complications.

Many really valuable papers have appeared dealing with this important subject, the general tendency appearing to regard such complications as due less to the anæsthetic than to the operation, or the pre-existing condition of the patient. Dr. W. PASTEUR [42] in the course of a closely reasoned article, advances arguments which appear to demonstrate that many or most cases of "pneumonia" following prolonged anæsthetisation for abdominal operations are, in fact, instances of massive collapse of the lung the result of traumatic "insult" to tissues and not a pneumonia at all. Some further observations on the matter will be found under Medicine.

The causation of glycosuria following ether has been investigated by Dr. J. H. KING, Dr. B. S. CHAFFEE, Dr. D. B. ANDERSON, and Dr. L. H. REDELINGS.[43] As is well known, RUSCHHAUFT, GEIS, WHITE, P. B. HAWK, and SEELIG had all found that glycosuria occurred after ether, and in the research referred to this finding was confirmed, and a causal relation was suggested between the extent of the hyperglycæmia and the concentration of the ether, as well as the length of time during which it was administered. It had been pointed out by previous workers, such as EDIE, MACLEOD, MOORE and ROAF, LEPINE and SEELIG, that excess of CO_2 or deficiency of oxygen, or splanchnic nerve interaction, may be the agency by which the result comes about. These possibilities were experimentally dealt with, healthy dogs being deeply anæsthetised with ether and the following conclusions come to. The reducing agent in the urine is dextrose and there is definite hyperglycæmia. The liver is the organ which furnishes the increase in the blood sugar, as is proved by the fact that when the liver is removed from the circulation by an Eck fistula both the hyperglycæmia and glycosuria disappear, while section of the splanchnic nerve fibres going from the cœliac axis to the liver does not prevent hyperglycæmia and glycosuria when ether is given.

An interesting paper is contributed by Dr. J. W. BOVÉE [44] on the effect of the Trendelenburg position on the excretion of urine. In the case of chloroform 82 per cent. and under ether 58 per cent. showed lessened secretion, a diminution which was slowly recovered from when the horizontal posture was resumed. This he considers should prove that great caution is needed in using this position for persons suffering from renal inefficiency and arterial or cardiac lesions. Dr. G. CHANDLER [45] is so impressed by the importance of posture in checking vomiting after ether that he has his patients sitting up to avoid the congestion of the medullary centres, as this in his view is the cause of vomiting. He points out that as persons suffering from heart disease cannot breathe when supine there can be little danger in the sitting position, at all events from the side of circulatory failure.

In the course of a discussion [46] on Post-operation Psychoses Dr. WEIR MITCHELL stated that his experience led him to believe that in nervous persons and those whose mental balance was unstable there was a great liability to nerve collapse after operations. This was peculiarly liable to occur where local analgesia was practised and the patient, even if free from pain, suffered psychic shock. One-third of the cases evincing psychic shock were males, two-thirds females; the severity of the operation appears to be no factor in producing the result. One of the gravest effects, because often persistent, is the supervention of delusions.

Treatment of Respiratory Failure During Anæsthesia.

It has been pointed out by Dr. WOOD and others that the common methods of producing respiration by manual arm movements fail to effect full pulmonary ventilation. ROTH [47] in considering the subject extols mechanical perflation, and Dr. J. O'DWYER in describing the O'Dwyer-Fell apparatus has recorded its efficacy, especially in children, although care has to be taken to avoid excessive force lest traumatic emphysema occur. It is also necessary to render the air warm and moist before it is perflated into the air passages.

Effects Produced by Ether.

Dr. GRAHAM [48] has studied the influence exerted by inhaled ether upon bacteriolysis, agglutination, and phagocytosis. He finds the first two processes are unaffected by ether, while in rabbits, as also, he believes, in man, the phagocytosis of streptococcus, pneumococcus, and staphylococcus is diminished. This effect may persist for some time, but this varies in individual cases. It is due, Dr. GRAHAM judges, not to serum conditions but to the actual destruction of the phagocytes. He advances the opinion that the solvent power of ether over fatty material is the prime factor at work, since although his experiments did not actually demonstrate this to be so, yet enemata of olive oil or subcutaneous injection of lecithin diminished in a marked degree the loss of phagocytic

action. Air forced through blood containing ether appears also to check the effect of ether upon phagocytosis.

Dr. W. P. GRAVES[49] records post-operative effects in 2000 cases, with the following results: 1089 were laparotomies with "open ether." 20 had pulmonary effects —8 bronchial pneumonia, 3 pleurisy, 9 bronchitis. In 911 cases—not laparotomies—there were 2 pulmonary affections, 1 bronchitis. The length of the anæsthesia did not appear to be a determining factor. He concludes that such complications are most liable to occur and prove fatal in septic cases and in patients desperately ill, aged, or feeble. Post-operative pneumonia does not, he believes, occur especially after severe shock, or when the anæsthetic is "taken badly." The colder months cause more cases; pre-existing foci of infection are roused into recrudescence. He points out that many cases can be avoided if a more careful examination of the patient is made before the operation and on succeeding days, while the condition is promptly treated so soon as recognised. KNECKE holds similar views and has suggested that in the case of abdominal operations the patients should be made to sit up the day after operation.

Dr. YANDELL HENDERSON[50] treats upon primary heart failure in normal subjects under ether. This valuable paper records the author's well-known views on acapnia, and asserts that such deaths as occur are due to the acapnic state brought about by hyperpnœa, itself the result of pain, alternating light anæsthesia and other causes. He regards LEVY'S experiments, referred to below, as examples, in cats, of acapnic states resulting in death through hypersusceptibility of the medullary centres engendered by that condition.

Effects Produced by Chloroform.

Dr. G. H. CLARK[51] has reinvestigated the effect of repeated doses of chloroform given to the lower animals. The point he believes that his research makes is that frequently repeated small doses lead to a more deleterious result than does a single massive dose. The drug was given: (1) by injection; (2) by the stomach; (3) by inhalation. The visceral changes noted were similar to those with which we are now familiar as arising in chloroform toxæmia. The question of dosing, however, really depends less upon the actual bulk of drug employed than upon the degree of its dilution at the moment of introduction. This has been overlooked by many of those who have studied the subject. That chloroform is a tissue poison acting lethally, either at once or after chronic toxæmia, has been proved, but we yet have to learn whether in a sufficiently diluted form chloroform ever leads to tissue changes of any serious import. The analogy with phosphorus will readily spring to the mind.

Dr. A. G. LEVY has contributed several valuable papers during the year. In "The Action of Chloroform when Intercurrent Asphyxia is Present"[52] the conclusions arrived at are interesting, as they limit the importance attached by some authorities to the dangers of heightened CO_2 content during chloroform narcosis, and thus corroborate the acapnia theory so strongly insisted upon by YANDELL HENDERSON and others. LEVY'S experiments, he believes, demonstrate that under chloroform cardio-inhibition is obscured or suppressed by complete asphyxia, but is variable during partial asphyxia. His results with ether are less definite, although somewhat similar. The paper should be carefully studied. Working with Dr. THOMAS LEWIS,[53] LEVY has investigated the curious effects upon the mammalian heart produced by low percentages of chloroform vapour. He connects the irregularities evinced with ventricular fibrillation, and finds that under full, but not excessive, dosage the conditions referred to do not occur. A similar communication appears in the *Journal of Physiology* (Vol. XIII.) and should be collated with Dr. G. C. MATHISON'S research in the same journal on the effects of asphyxia on the vaso-motor and other medullary centres. The CO_2 is apparently not a specific but a normal stimulus when the oxygen-lack fails to elicit a response.

Comparing the behaviour of ether and chloroform as regards the blood pressure, Dr. H. P. FAIRLIE considers that although depression is common to the two agents, recovery is more rapid in the case of chloroform. The probable explanation appears to be that in the case of ether no fall occurs until a very severe degree of nerve exhaustion due to excessive stimulation has been brought about; whereas chloroform acting as a vaso-depressor, so soon as its influence is withdrawn the centres resume their normal control.

The grave post-operative condition sometimes classed under the head of acidosis and sometimes as delayed chloroform poisoning has elicited several valuable papers giving the results of researches undertaken to elucidate the pathogenesis of the symptoms. Dr. CATES[54] examined 400 patients who went into the Boston City Hospital: 17 cases had acidosis on admission; 12 after an anæsthetic—viz., 10 after ether, 2 after N_2O; 17 developed it during their stay in the hospital but took no anæsthetic; 6 patients died. One patient who had acidosis on admission recovered under treatment and subsequently underwent a serious operation under ether without developing acidosis. Dr. E. MELLANBY[55] contributes a suggestive paper on cyclic vomiting, acidosis, and creatinuria in children. The cases occurred wholly independently of anæsthetics or operation. Most authorities concur in the valuelessness of the alkaline treatment. BALINI[56] has found rectal injections of glucose most useful. As the bowel speedily grows intolerant of glucose, he uses small doses and feeds the patient with bouillon and cheese, given by the mouth. BERENDES[57] prefers introducing the glucose into the tissues or by the mouth. He employs 5 per cent. or 7·5 per cent. in normal saline and infiltrates 1 to 2 pints.

Dr. P. B. HAWK,[58] after reference to the past work undertaken to elucidate post-anæsthetic glycosuria, details his experiments. He found that dogs subjected to different degrees of fasting upon being given ether showed that the greatest amount of dextrose appeared in the first urine and decreased subsequently. In fed dogs no uniformity of decrease was noticeable, nor in either case was there a regular relation between the specific gravity and the amount of sugar. He also observed that different animals reacted variously even though subject to similar narcosis. He came to the conclusion that the glycosuria was due primarily to the effect of ether in the direction of its stimulating effect in promoting the transformation of glycogen into dextrose. He believes that a certain amount of glycogen remains unchanged, stored, as he puts it, to meet such emergencies as starvation, and this the ether does not affect. That asphyxial dyspnœa may be a factor in causing the result he is ready to admit. Dr. D. J. M. SWAN[59] undertook an examination of patients, following Dr. HAWK'S line of research, and found in 16 cases that 10 showed no glycosuria either before or after ether; 1 revealed none before but some afterwards, but in this case there was a history of previous glycosuria; 2 had glycosuria both before and after; 1 unexamined before showed the condition after; and 2 having none before

developed a high degree afterwards—these patients were aged 60 and 80, and one died.

The Anæsthetics Bill.

The attention of Parliament has been so completely preoccupied that no steps have as yet been taken to bring before it the legislative proposals relating to the administration of anæsthetics desired by the medical profession, but the General Medical Council intends to press upon the Government the urgency of this among other medical matters.

PUBLIC HEALTH.

Plague and Cholera.

In our review of 1910, which for convenience began with notes on special features characterising the prevalence of infectious diseases in this country during the year, we gave the first place to plague, as in the autumn of 1910 this disease had been found to have caused a considerable epizootic among rats and other rodents in certain parts of Suffolk, and had occasioned a few cases in man of the pneumonic type.

During 1911 only one instance of human plague arising in this country came to notice, and this occurred in October in the area where plague infection had been demonstrated the year before. The case also was of the pneumonic type. Local efforts were made during the year to destroy rats in the invaded areas, and plague-infected rats have in a few cases been found among the large numbers which have been destroyed. The work has been undertaken by the local sanitary authorities under the direction of the Local Government Board, which undertakes the bacteriological examination of all suspected rodents. While the history of plague-infection in Suffolk has been reassuring, vigilance is still needed in order that the rat population of the affected localities may be exterminated, or at least reduced to the lowest limits by systematic destruction and prevention of their access to food.[1] The reports of the medical officers of health of the port sanitary authorities[2] show that rat destruction is still carried out vigorously at the principal ports, and no new instance of the introduction of plague infection has been brought to light. The general progress of plague outside these islands, and particularly its appearance in Siberia and Northern China as a serious epidemic of the pneumonic variety, is referred to in the section on exotic disease below.

The extensive prevalence of cholera in Mediterranean ports, particularly in Italy, gave rise to some fear of the importation of this disease during the autumn, but no case of cholera has been known to have occurred in the United Kingdom during the year. At the time of writing an International Sanitary Conference, attended by official delegates from all parts of the world, is in session at Paris, to consider international agreements for the control of cholera, yellow fever, and plague.

Measles and Whooping-cough.

The prevention of measles has been much discussed during the year. The striking reduction which has been effected in the incidence of many of the more common infectious diseases during the past half-century makes more conspicuous the fact that measles is not materially diminishing either in its incidence or in its mortality. In London the position has already been alluded to briefly. During the five years 1905-09, measles caused 9301 deaths, while all the infectious diseases at present compulsorily notifiable caused 8585 deaths, and when it is remembered that recovery may be followed by retarded growth, development of latent tuberculosis, deafness, and other serious consequences, it is obvious that the mortality from measles is not a complete index of the mischief wrought by it. In the early months of 1911 measles was exceptionally prevalent in several parts of the country, but especially so in London, where for some weeks the number of deaths was between one and two hundred every week. London medical officers of health found that their means of coping with the outbreak were in many ways inadequate. The disease seemed to have been widely spread through infant schools which ought to have been closed, while school teachers and school attendance officers failed to inform the medical officers of health of cases of measles until it was too late to arrange for the class to be temporarily suspended during the critical days or for other precautions to be taken. Cases frequently came to light in tenement dwellings where family to family infection might have been prevented by knowledge of the first case, and many medical officers pressed for at least a partial notification of measles, limited to the first case in a household. Home visiting in many cases revealed the great need for institutional treatment in the interests of the patient. The outbreak also caused stress to be laid on the need for the amendment of the Children Act, 1908, so to enable Section 12 to be utilised by sanitary authorities to induce parents to provide medical aid for cases of measles. As a result of representations made to the London County Council and Government departments concerned, some useful changes were introduced. Although measles was not made notifiable generally, special instructions were given to secure the better notification of school cases, and arrangements were made by the Metropolitan Asylums Board[3] for the reception of a number of cases of measles (in the first instance limited to those for whom orders were obtained through the Poor-law authorities) on the recommendation of the medical officer of health. An official memorandum on measles prevention generally, by the medical officer of the Local Government Board, was issued to sanitary authorities in March last.

The arrangements of the Metropolitan Asylums Board for the reception of measles extended to whooping cough, and it may be observed that in the country generally the use of the isolation hospitals for selected cases of both whooping-cough and measles is increasing. A useful report by Dr. A. K. CHALMERS[4] on the practice of Glasgow in this respect was issued during the year.

Scarlet Fever.

Although much careful research has in past years been undertaken with the object of differentiating classes of streptococci and separating a variety which is specially associated with scarlet fever, the promise of the discovery of a true streptococcus scarlatinæ has not been fulfilled. The last report of Dr. M. H. GORDON,[5] who has made this subject specially his own, shows that the scarlatinal variety of streptococcus may be found in the normal throat and in the throat during diphtheria. The negative result of these thorough investigations should give important stimulus to the further study of the bacteriology of the disease, which is greatly needed. A valuable discussion on scarlatinal and other sore throat caused by infected milk took place at the Epidemiological Section of the Royal Society of Medicine in February on a paper by Dr. W. G. SAVAGE. While accepting as demonstrated the fact that outbreaks of scarlet fever have repeatedly been caused by milk from particular cows presenting sores on the udder, and not by direct infection of the milk from a human source, Dr. SAVAGE put forward the hypothesis that the cow has

probably received a past infection from a human case, and in certain circumstances continues to furnish infected milk without herself suffering from any specific disease.

Small-pox.

Mild outbreaks of small-pox were reported during the year in a few English counties. In London about 70 cases have been notified and some 200 in the rest of England. It remains to be seen whether the reappearance of epidemic small-pox, which has generally been anticipated during 1910–12 will only be manifested on this quite limited scale.

Enteric Fever and Diarrhœa: Some Effects of the Hot and Dry Summer.

Some important official reports were issued during the year bearing upon the prevention of enteric fever. The importance of attention being paid to sewage pollution of cockles, mussels, and other shell-fish, in addition to oysters, has been recognised for some time, and there is now no doubt that consumption of these molluscs may be responsible not only for sporadic but sometimes also for epidemic occurrence of the disease. The late Dr. BULSTRODE was for some years engaged in a survey of the conditions of all the gathering-grounds round the English littoral in regard to risk of sewage pollution of cockles and mussels on the lines of his well-known inquiry into oyster layings. His report on this survey showed the various places round the coast at which dangerous pollution exists, and will be invaluable as a basis of preventive measures and for reference when shell-fish are suspected of carrying infection. A report on inquiries into the sudden outbreak in Eccles in 1910, which affected 142 cases, was made by Dr. S. M. COPEMAN during the year under review, and showed beyond question that its cause was the consumption of ice-cream sold in the streets. The ice cream had been made in a tenement house in Manchester and apparently had been infected by an unrecognised case of enteric fever, or by a carrier, in the course of its preparation. Dr. W. H. HAMER, in an analysis of local prevalence of enteric fever in London,[6] has adduced strong circumstantial evidence that its distribution was determined by the consumption of fried fish from particular shops, the fish specially suspected being ungutted and presumably having reached the market in an infectious condition.

The prolonged and in many respects welcome dry summer gave rise to considerable shortage of many local water-supplies. London, owing in large measure to the additional storage now available for Thames water and to inter-communication of the trunk mains of the different systems escaped any water famine, but larger provincial towns, including Manchester, were put on a restricted service, and some smaller towns and villages suffered severely from shortage. The break-up of the prolonged drought was happily not attended by any large water-borne epidemic. But although the returns are not yet available, it appears probable that the climatic conditions have been favourable to the increase of endemic enteric fever in several places especially in those northern towns where middens and pail, privies are still largely in use.

As regards infantile diarrhœa, there is no doubt that the customary effect of a hot summer and autumn, through flies or otherwise, has been exercised; the Registrar-General's returns for the third quarter of 1911 show a total infant mortality in England and Wales equal to 201 per 1000 births, a proportion which is 60 per 1000 above the average in the ten preceding third quarters, and higher than that in any corresponding quarter since 1901, when the proportion was 208 per 1000. The London increase was, however, comparatively low. The figures will no doubt disturb the favourable statistics of recent years in towns where special efforts have been made to reduce infantile mortality, but they should not in any way be made the reason of relaxing these efforts, which are at no time of more value than in years when the climate is favourable to diarrhœa mortality.

As a mere matter of record, and especially as the industrial unrest of the summer was so frequently connected with the weather, we may here allude to the heavy strain placed on the sanitary staff of many of the chief towns by the accumulation of perishable foodstuffs during the strikes at the docks and in the carrying trades.

Epidemic Poliomyelitis.

General recognition of poliomyelitis as an epidemic and presumably infectious disease has come tardily in this country, which has not hitherto experienced such outbreaks on a large scale such as those which have occurred in New York, Scandinavia, and Northern Germany, and consequently the disease has received less attention from public health authorities than cerebro-spinal meningitis, with which it is not infrequently confused. The subject has been dealt with in a previous section of this report, but its public health bearing is obvious.

Tuberculosis: Final Report of the Royal Commission; Compulsory Notification of Pulmonary Tuberculosis.

The Royal Commission on Human and Animal Tuberculosis issued its final report in July.[7] The essential identity of tuberculosis in man and cattle, and their intercommunicability under certain conditions, had been established in interim reports, based on a large amount of experimental work, which had already been generally accepted as finally disposing of the contention that the risk to man of infection from bovine sources is non-existent or of a very minor importance. The final report reviewed the results of the whole of the work of the Commission at the experimental farms at Stansted during the nine years of the inquiry. It has shown that a large part of the tuberculosis of early life must be attributed to infection of the bovine type and of bovine origin, and that exceptionally pulmonary tuberculosis in man is also to be attributed to bovine infection. The differential characters of tuberculosis in man, various mammalia, and birds; the stability of different varieties of tubercle bacilli in their cultural characteristics and virulence; the different susceptibility of different species to tuberculosis of the same animal origin; the peculiar bacteriology of lupus, and many other matters have been investigated with a thoroughness which is beyond praise, and the report of Sir W. H. POWER and his colleagues, together with the supplementary volumes which are now appearing, have placed a really great achievement to the credit of British scientific research. The fifth volume of the appendix to the final report, written by Dr. ARTHUR EASTWOOD, appeared just before Christmas, and in it the author observes that underlying all the mammalian viruses investigated by himself there is an essential unity of characteristics.

We have already dealt with the question of notification.

Among the many notable contributions to the literature or policy of prevention of tuberculosis which have appeared during the year we may refer here to the proceedings of the National Association for the Prevention of Consumption, opened by Mr. JOHN BURNS; the statements as to the uses of sanatoriums, prepared by Sir CLIFFORD ALLBUTT, SIR L. BRUNTON, Dr. A. LATHAM, and Sir W. OSLER on behalf of the Welsh National Memorial;[8] and the observations of Dr. A. NEWSHOLME in the annual report of the medical officer of the Local Government Board for 1910–11. The importance of the factor of heredity in phthisis was the subject of a useful discussion at the Royal Society of Medicine in April,

[6] Annual Report of the Medical Officer of the London County Council for 1909.

and a paper was contributed by Dr. W. BULLOCH and Mr. M. GREENWOOD, jun.

Industrial Hygiene; Effect of Humidity on Health; Industrial Cancer and Lead Poisoning.

The report of the Home Office Departmental Committee on Humidity and Ventilation in Cotton-weaving Sheds,[9] issued early in the year, gave the results of inquiries as to the physiological condition of weavers working in warm and artificially humidified atmospheres. As a class these weavers are found to be in generally weak physical condition, with poor appetite and frequent indigestion. These conditions are to be attributed to the special conditions of their work. The influence of warm moist atmosphere is to diminish the difference between the internal temperature of the body and that of the peripheral parts, thus establishing a more uniform temperature of the body as a whole and throwing a tax upon the powers of accommodation, which is indicated by the low blood pressure, notwithstanding the rapid pulse-rate. Prolonged exposure to a hot and humid atmosphere appears to be more injurious than exposure to an even higher wet bulb temperature for a short time. The general view of the physiologists consulted by the Committee was that the health and comfort of the workers are dependent rather on the wet bulb temperature than on the dry bulb temperature, or the relative humidity, or the absolute humidity. The Committee found it impracticable to recommend that artificially humidifying the air of cotton weaving sheds should be abolished, but made numerous recommendations for preventing its most serious effects upon health, including the ultimate prescription of a wet bulb temperature above which the humidifying must cease. Other noteworthy observations, such as those on the differences in the conductivity of the packing of steam-pipes, were contained in the report. A Bill empowering regulations to be made was enacted during the session, and regulations on the lines of the report are now being prepared. Among the dangerous trades specially dealt with during the year in the department of the Chief Inspector of Factories, mention may here be made of the manufacture of briquettes from coal-dust by the addition of pitch, in which damage is caused to the eyes by the pitch-dust, and "pitch-warts" are often formed in the skin which may lead to carcinoma. Draft regulations have also been issued to supersede existing special rules for the manufacture and decoration of earthenware and china and for the making of transfers, and will give effect to the main recommendations of the Departmental Committee of 1910. Their object is to secure more stringent precautions for the prevention of lead poisoning and lung mischief—especially by the suppression of dust.

The Housing Acts.

The duties of medical officers of health have been very considerably increased by the work of reporting houses as unfit for habitation, and of advising as to closing orders for insanitary property, which is entailed on them by the Act of 1909, and where a reactionary local council is concerned these duties are often particularly thankless. A recent official return shows that there has been a large total increase in the number of insanitary houses and areas dealt with by local authorities in 1910–11, as compared with previous years, but that only a minority of these authorities have so far shown any activity in applying the Acts or acting on the advice of their medical officers.

Medical Inspection of School Children.

The accounts of the reports of school medical officers which appear almost weekly in THE LANCET make it nearly unnecessary to refer to the progress that continues to be made in the organisation of medical inspection of children on entry and on leaving the public elementary schools, as a consequence of the Education (Administrative Provisions) Act, 1907. The extent and consequences of this inspection have quite lately been fully described by Sir GEORGE NEWMAN in the annual report of the chief medical officer of the Board of Education for 1910, reviewed in our issue of Nov. 4th. Here we would merely refer to the fact that according to that report school medical officers, working under schemes approved by the Board of Education, have been recognised by that department in 305 of the 322 local education areas in England and Wales, and that the rapid progress which has been made in the organisation of the complex system comprised in "school medical inspection" has been one of the most striking features of the year.

A substantial advance has already been made in this work in London, which was notoriously behind the rest of the country in efficiency, and this, we believe, will be accelerated by the impending reorganisation of the medical department of the London County Council, which will place the educational medical work under the direction of the county medical officer of health.

During the year the Board of Education issued a memorandum by Sir GEORGE NEWMAN on physical training in secondary schools,[10] in which the importance of exercises based on the "Swedish system" coupled with control by the school medical officer was insisted upon, while a further circular, issued in the autumn,[11] emphasised the need for control by the school medical officer over the arrangements made by education authorities under the Education (Provision of Meals) Act, 1906.

Milk- and Food-supply.

Dairy farmers' associations in the North of England have been actively agitating during the year against the present system of controlling the adulteration and impoverishment of milk by the application of the so-called "presumptive" chemical limits laid down in the official milk regulations, contending that the farmer who supplies unadulterated milk from a herd or a cow which yields a poor quality milk, under 3 per cent. of milk fat, is at present unduly penalised. Sanitary authorities, who know that milk with a much higher yield of fat can be supplied if it is insisted on, naturally oppose these views, but for different reasons would welcome the disappearance of the present unworkable system. The solution to the matter, which causes infinite trouble to all concerned, will probably be found in the prescription of "absolute standards" and their control by simplified administrative methods.

The question of the declarations which should be required to be made on tins of condensed milk was dealt with in a report by Dr. F. J. H. COUTTS to the Local Government Board,[12] which showed that condensed skim-milk is still frequently used to a dangerous extent for infant feeding. Other notable reports in the same series have related to the nutritive value of different kinds of bread,[13] and to the practice of bleaching flour by nitrogen peroxide and increasing its water-absorbing capacity by the addition of various chemical substances known in the trade as "improvers." These very objectionable practices have been widely adopted in the trade, and unfortunately have not hitherto been sufficiently brought under the control of the Adulteration Acts.

The Census: Registrar-General's Reports.

The tenth decennial Census was taken on April 3rd, and the preliminary tables were issued in June. The total population of England and Wales was 36,075,269, of Scotland 4,759,445,

[9] Second Report, 1911, Cd. 5566.

[10] THE LANCET, July 22nd, 1911, p. 235.
[11] THE LANCET, Sept. 2nd, 1911, p. 696.
[12] THE LANCET, Sept. 16th, 1911, p. 833.
[13] THE LANCET, Sept. 9th, 1911, p. 773.

and of Ireland 4,381,951. The increase of population which had taken place since the Census of 1901 was much below that which was estimated by calculation from the previous intercensal periods.[14] An actual fall of population had taken place in many rural areas, notably in Scotland. Nearly all the larger towns showed a conspicuous diminution of the population in their central parts; in some cases, where municipal boundaries enclose a minimum of "suburb," the population of the town as a whole had diminished.

In London, the population of the administrative county was 4,522,961, less by 13,306 than that in 1901. In so-called "Greater London," however, there were 7,252,963 inhabitants, over half a million more than at the previous Census.

The publication of the Census figures has shown that many estimated death-rates throughout the country have been seriously understated during the last few years. In the interest of accurate statistical work it may be hoped that the usual official objection to an intermediate Census may be overcome before 1916.

During the year the Registrar-General has announced important changes in the tabulation of vital statistics, which include the substitution of local government administrative areas for registration districts in his annual report, adoption of the recently revised international classification of causes of death, and distribution of "transferable" deaths on a recognised system to the districts to which they properly belong. These changes, which are being adopted in the preparation of the report for 1911, will be of the greatest advantage to medical officers of health and to statisticians generally.

Sanitary Legislation.

Besides the National Insurance and various local Bills, few measures bearing on public health administration have passed through Parliament during the session. The Milk Bill, as stated above, was not introduced, and the Health Visitors and Midwives Act Amendment Bills were dropped. In view of our own share in directing attention to the subject, we are glad to record that Mr. BURNS'S useful little Bill providing for the washing and cleansing of rag flock passed through all its stages and will take effect after October, 1912.

Conferences and Exhibitions.

We have already referred to the meeting of the National Association for the Prevention of Consumption held in London in July, and may also recall the Congress on the Prevention of Destitution, the opening meeting of which, at the Albert Hall, was the occasion of a noteworthy speech by Mr. A. J. BALFOUR. The International Congress on the Prevention of Infant Mortality, held at Berlin in September, was attended by numerous delegates from Great Britain. The Seventh International Congress on Tuberculosis, which was to have been held in Rome in September, was postponed till 1912. Although the British Government was not represented at the International Exhibition of Hygiene at Dresden, an excellent British section was organised by voluntary effort and subscription.

The Coronation Celebrations.

We may note that while many of the events of the year, such as the Census, the Insurance Act, the hot summer, or the compulsory notification of tuberculosis, will help to make 1911 memorable in public health records, the central national event, the coronation of His Majesty King GEORGE V., was happily without any public health history, notwithstanding the exceptional movements and aggregations of population which marked the celebration of that great ceremony.

[14] THE LANCET, July 15th, 1911, p. 174.

TROPICAL AND EXOTIC DISEASES.

Bureaux and Bulletins.

The year 1911 has been one of marked activity and enterprise in the department of tropical medicine, evidence of this being afforded by the establishment of bureaux devoted to the investigation of special infections, and the publication of bulletins relating to work done at home and abroad in connexion with special diseases. The Central Malaria Bureau in India has now started a periodical, under the title of *Paludism*, for the assistance of those engaged in the campaign against malaria in India and elsewhere. Three very instructive numbers have already appeared, the joint editors being Major S. B. JAMES, I.M.S., and Major S. R. CHRISTOPHERS, I.M.S. The newly founded Yellow Fever Bureau, which the Liverpool School of Tropical Medicine has established, began the issue of a monthly journal, under the name of the *Yellow Fever Bureau Bulletin*, last May, its editor being Dr. HARALD SEIDELIN. By arrangement with the honorary managing committee of the Sleeping Sickness Bureau a new bulletin, on the model of the *Sleeping Sickness Bureau Bulletin*, has just published its first number, dealing with the forms of disease caused by leishmania, and under the title of the *Kala-Azar Bulletin*. It will appear quarterly, under the editorship of Dr. C. M. WENYON, protozoologist of the London School of Tropical Medicine, who has quite recently returned from Bagdad and Aleppo, where he has been studying the way in which "Oriental sore" is spread. It is intended that this new periodical will do for leishmaniosis what the *Sleeping Sickness Bureau Bulletin* has already done for the study of trypanosomiasis.

Commissions and Investigations.

Admirable work continues to be done by the Committee for the Study of Malaria in India. The Government of India have given 5 lacs of rupees to endow an Indian Research Fund with a view to assist in defraying the cost of research work in connexion with public health and hygiene. A Sanitary Conference was held in Bombay in November, at which the Minister of Education urged wealthy Indians to contribute to the funds for carrying out a much needed sanitary campaign in India. Mr. ANDREW CARNEGIE has promised £1000 a year for three years to endow entomological scholarships to enable three suitably qualified young men being sent to America to study the practical application of entomology, so that they may in time be able to proceed to Africa, where the services of trained entomologists are so much needed. The reconstituted Sleeping Sickness Commission appointed by the Royal Society returned to Central Africa in November to continue their investigations under the leadership of Colonel Sir DAVID BRUCE, C.B., F.R.S., his colleagues being Captain A. E. HAMERTON, D.S.O., and Major DAVID HARVEY, R.A.M.C., along with Professor R. NEWSTEAD, the eminent medical entomologist of Liverpool. Lady BRUCE again accompanied the Commission to Africa to share in their labours. A Sleeping Sickness Commission appointed by the British South Africa Company proceeded in 1911 to Rhodesia to investigate the disease there, the members being Dr. A. W. MAY, principal medical officer of Northern Rhodesia; Dr. A. KINGHORN, of the Liverpool School of Tropical Medicine; and Dr. J. R. LEECH, of the Rhodesian Medical Staff; they were accompanied by a trained entomologist and a bacteriologist. An expedition despatched by the Liverpool School of Tropical Medicine, including Dr. JOHN L. TODD and Dr. S. B. WOLBACH, visited the West African Colony of the Gambia to make further inquiry into the value of gland puncture in the diagnosis of sleeping sickness. In German East Africa Professor F. K. KLEINE and Dr. M. TAUTE of the German Sleeping Sickness Commission demonstrated experimentally

that the virus of human trypanosomiasis can be transmitted by the agency of glossina morsitans; and in Rhodesia Dr. KINGHORN also succeeded in transmitting T. gambiense by means of G. morsitans, a circumstance which will help to explain the occurrence of sleeping sickness in regions where G. palpalis is not found. The progress of our knowledge of this disease up to the present time was summarised by Dr. C. A. BAGSHAWE, director of the Sleeping Sickness Bureau, in a paper read before the Society of Tropical Medicine in October.

Considerable advance in our knowledge of kala-azar has taken place in 1911, contributions to it having been made by Dr. C. NICOLLE (Tunis), Dr. G. PIANESE, Dr. C. BASILE, and Professor G. FRANCHINI. A Commission in the Anglo-Egyptian Soudan has been investigating the subject of kala-azar in that region. An excellent summary of what is known concerning kala-azar in its various forms was published in the October number of the *Quarterly Journal of Medicine* by Lieutenant-Colonel Sir W. B. LEISHMAN, F.R.S. A second Pellagra Field Commission, consisting of Dr. L. SAMBON and Dr. J. CHALMERS, left London in August for Hungary to study the disease there, and afterwards to continue their investigations in other parts of Europe. They were subsequently joined by three American investigators—viz, Professor M. HAASE, Dr. H. P. COLE, and Dr. J. MARTINEZ. The etiology and treatment of leprosy have received considerable attention during the year, contributions to the literature of the subject having been made by Major E. ROST, I.M.S., Captain T. S. B. WILLIAMS, I.M.S., Dr. H. BAYON, Craggs Investigator of the London School of Tropical Medicine; Dr. LINDSAY SANDES, Robben Island Leper Colony; Mr. E. C. LONG, Basutoland; and Dr. K. S. WISE, British Guiana.

The causation of beri-beri has been freely discussed during 1911, among others by a group of investigators in the Philippine Islands, including Major WESTON P. CHAMBERLAIN and Major HORACE D. BLOOMBERG, along with Captain EDWARD D. KILBOURNE and Captain EDWARD B. VEDDER, all of whom are officers in the Medical Corps of the United States army, and Dr. VICTOR G. HEISER, Director of Public Health in the Philippines. At home Dr. G. C. E. SIMPSON and Mr. E. S. EDIE, B.Sc., of the Liverpool School of Tropical Medicine, and Messrs. E. A. COOPER and CASIMIR FUNK of the Lister Institute have also published the results of their investigations. Major E. D. W. GREIG, I.M.S., inquired into the prevalence of beri-beri in Calcutta and presented an official report on the subject. At the November meeting of the Society of Tropical Medicine and Hygiene the etiology of beri-beri was very thoroughly thrashed out in a discussion in which, along with others, the following high authorities took part—viz.: Professor H. SCHAUMANN, of Hamburg; Professor AXEL HOLST, of Christiania; Dr. H. FRASER, of Kuala Lumpur; and Dr. C. J. MARTIN, F.R.S., Director of the Lister Institute. The subject of sprue is to be investigated in Ceylon by an expedition about to be sent thither under the charge of Dr. P. H. BAHR, of the London School of Tropical Medicine.

The Incidence of Exotic Disease.

Following our practice of former years we give below a short sketch of the incidence throughout the world in 1911 of the three principal exotic diseases which concern this country, its colonies and its dependencies—viz., cholera, plague, and yellow fever. We also give a short summary of what is known regarding the behaviour of small-pox abroad during the year, this disease being a constant menace and one that grows more serious day by day owing to the increasing neglect of vaccination and revaccination.

Cholera in Europe.

Cholera, which had been ravaging Russia since 1907, and which had attacked in that empire during 1910 no fewer than 230,000 persons, of whom about 110,000 died, showed a greatly diminished incidence in 1911; up to the end of October rather less than 3500 cases and 1600 deaths had been reported in the whole of Russia. The governments situated in the basin of the Volga, particularly Samara, supplied nearly the whole of the cases—that is, about 3000 out of the total 3500—leaving only 500 cases to be distributed over 24 other governments and provinces. Cholera was reported in small amount in Greece, Montenegro, Bulgaria, Servia, and Roumania; and there were localised groups of cases in Austria, at Vienna, Trieste, Capodistria, Torre, Arbe, Cattaro, and other places, though the total cases altogether did not quite reach a hundred. Eleven counties in Hungary were invaded by cholera during the year, but up to the beginning of November only about 200 cases altogether came under observation; while in Croatia-Slavonia, including the port of Fiume, about 26 others were notified.

The worst sufferer from cholera in Europe during 1911 was the kingdom of Italy, in which, up to the end of October, 15,459 cases and 5757 deaths had been officially reported; these were distributed over 49 provinces, including some in the islands of Sicily and Sardinia. The provinces which contributed the largest number of cases were Naples, Palermo, Caserta, and Salerno. It will be remembered that the disease broke out in Southern Italy in the summer of the previous year, and that it had subsided by the end of December. The recrudescence of 1911 began in June, the epidemic reaching its height in August; by November it had practically ceased. Some regrettable outbursts of violence on the part of the mob against municipal authorities, doctors, and nurses occurred during the course of the cholera prevalence. In one instance which occurred not far from Rome, the rioters overpowered the military guard and stormed the cholera hospital, shouting, "Death to the doctors and nurses," and ultimately carried away the sick to their homes. The mob were under the impression that the cholera patients were being purposely poisoned in the hospital. The same mob wrecked the town-hall, threatening to kill the mayor and his staff, who, however, escaped.

Cholera broke out at Malta in November, and up to the end of the month about 120 cases and 70 deaths had been recorded. From Italy the infection was carried to Marseilles, but detailed information as to this outbreak is not easy to obtain. It is, however, stated that in one of the lunatic asylums in the town some 80 cases and 51 deaths were certified, as well as a number of other cases among the general population. Up to mid-November scattered cases were still occurring in Marseilles. The French fleet stationed off Toulon suffered from an outbreak of cholera in November, 70 sailors being attacked. It is said that previous to this two cases had occurred in the town of Toulon. In Spain, at Barcelona, and in the province of Catalonia, near Taragones, there was an outbreak of cholera, over 800 persons being attacked during August and September, Vendrell and La Riera districts being special sufferers.

Cholera in North Africa.

Cholera appeared in Tunisia early in August, and up to October some 200 cases had been reported, the chief places invaded being the town of Tunis and the districts of Bizerta and Medjez-el-Bab. The prevalence of cholera in Tripolitania was also notified in October, but owing to the military operations little definite information has been published. It is known, however, that the disease existed at Tripoli, not only among the invading Italians, but also among the Turkish troops and their Arab auxiliaries. The

infection was brought to Algiers and also to Port Said by ship, but did not spread in either instance. As already mentioned, the infection was conveyed by refugees to Malta from Tripoli. The epidemic of cholera in the island of Madeira which was prevailing at the end of 1910 continued during the early weeks of 1911, during which period 327 additional cases and 98 deaths were certified, raising the total attacks in the winter epidemic of 1910–11 to 1774 and the deaths to 555.

Cholera in the Near East.

The disease was epidemic in Turkish territory during the whole of 1911. At Constantinople more than 2600 cases were notified, and of these nearly 1500 proved fatal. Cholera was also prevalent in the following towns with their surrounding districts—namely, Adrianople, Salonica, Monastir, and Uskub. In Arabia the provinces of Hedjaz, Yemen, and Asir were invaded, and outbreaks occurred in several towns, including Mecca, Medina, Jeddah, Janbo, and Hodeidah. A few cases also were discovered at the station on the island of Perim among the pilgrims, and at the quarantine station on the island of Camaran nearly 100 cases were detected among the many pilgrims detained there under observation. In Mesopotamia many districts were affected, and among others may be mentioned Bagdad and Basra. In Asia Minor the disease was widely diffused, a number of the vilayets being affected, including Diarbekir, Erzeroum, Trebizonde, Sivas, Angora, Kastamouni, Brousse, Konia, and Aïdine. In the city and port of Smyrna more than 1200 cases were reported, of which over 700 terminated fatally. In Syria a number of towns and districts were invaded, and epidemics occurred at Damascus, Jaffa, and Tripoli (in Syria). In Persia during the summer months of 1911 cholera was specially prevalent near the Turkish frontier, at Mohemmerah on the Shatt-el-Arab, Ahwaz, Abadan, Schouster, as well as at some other places situated along the banks of the river Karun, and in the region at the head of the Persian Gulf. Late in November a cholera outbreak was reported in the Bahrein Islands off the Arabian coast in the Persian Gulf.

Cholera in India and the Far East.

In India cholera was, as usual, very prevalent during the year, and so far as can be gathered from the provincial returns, which, however, only in most instances bring the figures up to the beginning of August, there were in that period nearly 200,000 deaths certified as due to this cause. The United Provinces of Agra and Oudh seem to have suffered the most, for about 77,000 of the total deaths from cholera in India were referred to that administrative area. In the Bengal Presidency, which came next, there were up to August more than 53,000 deaths, in Eastern Bengal and Assam nearly 30,000, and in the Presidency of Madras over 25,000, so that these four provinces accounted for 185,000 of the total 200,000 cholera deaths reported in India up to August.

An explosive outburst of cholera occurred in November at Benares in the United Provinces in the military cantonment occupied by the Royal Scots (Lothian) Regiment, but it was quickly subdued. In Ceylon cholera was somewhat prevalent from May to July in the coolie station at Ragama and at Colombo, altogether about 360 cases coming under official cognisance. At Singapore in the Straits Settlements the disease was epidemic from March to October, and also in the province of Perak and on the island of Penang. From January to June cholera was seriously prevalent in the kingdom of Siam and especially at Bangkok, where nearly 1600 fatal cases were recorded. In French Indo-China numerous outbreaks occurred in Annam, Cambodge, Cochin-China, Laos, and Tonkin. Cholera was acutely epidemic during the year in the Dutch East Indies, and especially in the island of Java at Batavia, where over 1400 cases were notified, at Samarung, with about 800 attacks, and also in less amount at Soerabaya, Passoeroean and a number of other places. Outbreaks, too, occurred in the island of Sumatra, at Palembang, and along the east coast, where over 700 cases came under notice. The disease also appeared in the islands of Borneo, Celebes, and the Moluccas, as well as in some of the smaller islands of the Malayan Archipelago.

There was comparatively little cholera during 1911 in the Philippine Islands, only about 220 cases being notified up to October; the city of Manila practically escaped from the disease during the year. Only a few cases were detected in Japan, and these were reported at Osaka and Kobe; isolated ship-borne cases were also notified at the ports of Nagasaki and Yokohama. China seems to have suffered from a quite trivial invasion by cholera in 1911, as only sporadic cases came under observation at Hong-Kong, Amoy, Swatow, Hoihow, Nanking, and Hankow. In Manchuria there was a limited outbreak in August and September at Dalny (or Dairen), where about 100 cases were reported, and also some others at Kinchow. In the Hawaiian Islands the infection was imported into Honolulu, where early in the year about 40 cases and 28 deaths were recorded.

Cholera in America.

During the summer months of 1911 a number of ships carrying emigrants from Mediterranean ports, and chiefly from Naples and Palermo, arrived at New York. In six of these steam vessels 25 cases of cholera were reported at the quarantine station, two of which occurred in persons who had undergone five days' observation and had proceeded to their destinations outside New York. In addition, a number of other persons were found to be cholera-bacilli carriers. A single shipborne case occurred at Boston. These instances led the United States authorities to increase the restrictions placed upon arrivals from infected ports. A carrier of cholera bacilli was found at the Canadian quarantine station at Grosse Isle, and in response to a request from the United States Government Canada agreed to impose further restrictions so as to exclude infection by Canada.

Plague in Asia and Oceania.

Plague continued its ravages in India during 1911, nearly 800,000 deaths being ascribed to this cause up to the end of October—that is, in a period of 10 months. The plague deaths in India in 1910 were 512,605, and in 1909 178,808, so that it is certain that when the returns for 1911 are completed they will show a considerable increase in the amount of the disease as compared with the two previous years. Among the Indian provinces which suffered most were the United Provinces of Agra and Oudh with over 320,000 fatal cases, the Punjab with more than 200,000, Bengal with about 70,000, and the Presidency of Bombay with more than 96,000. Most of the other provinces showed a decreased mortality from plague. Eastern Bengal and Assam still maintained its remarkable immunity from epidemic plague, only 22 deaths from this cause being certified in 1911 in its population of about 34,000,000. The Madras Presidency, too, continued to show its previous comparative immunity from the disease, for only about 11,000 plague deaths occurred among its population of over 41,000,000.

In the Straits Settlements a few scattered cases of the disease were reported at Singapore. A somewhat severe outbreak occurred in the Dutch East Indies, on the Island of Java, affecting seriously a number of districts, especially Malang, where about 1600 cases were notified, and in a less degree Batavia, Kediri, and Soerabaya. About 100 cases of plague were reported in Bangkok, the capital of Siam. The disease was widely disseminated throughout Indo-China, about 1230 cases being notified in Annam during the first seven months of the year, about 600 in Cochin-China, nearly 400 in

Cambodge, but only a few cases in Tonkin. In the Quang-Tcheou-Wan territory, leased by China to France, nearly 2000 deaths from plague were certified. In Asiatic Russia sporadic cases were reported in a number of localities as in previous years.

In the Chinese Empire the main manifestation of the disease was the disastrous epidemic of pneumonic plague which swept across Manchuria from west to east, beginning in the winter months of 1910 and extending into the early part of 1911, killing practically all whom it attacked, the death-roll reaching about 50,000. The infection was carried across the Gulf of Pechili into the province of Shantung, in which, at Cheefoo and other places, about 3000 further deaths occurred, and into the province of Pechili, where a number of fatal cases were recorded at Tientsin, Peking, and elsewhere. The disease was also prevalent during part of the year at Hong-Kong, Canton, Swatow, Shanghai, Pakhoi, and Lien-Tcheou-Fu. Virulent epidemics were reported at Chau-Chow-Fu, when about 6000 fatal cases occurred, and at Chao-Yang, where some 2000 perished during the epidemic. In Japan a few cases were certified in Osaka, and in the island of Formosa, chiefly in the Kagi prefecture, where nearly 400 cases were notified. A single ship-borne case from Amoy was landed at Merivales in the Philippine Islands. There was little plague in Oceania; the only cases reported were several in New Zealand, at Auckland and Onehunga, where infected rats also were found, and in the Hawaiian Islands at Honokaa and Kapulena. Rat plague was reported in these islands at Hilo and Aiea.

Plague in America.

Plague appears to have become endemic in most of the South American States. In Brazil it appeared during 1911 at Rio de Janeiro, Para, Pernambuco, Sao Paulo, and San Conçalo, though apparently in no very great amount. At Asonçion and in its vicinity in Paraguay the occurrence of some virulent pneumonic cases was reported in August and September. Among the victims were two young Paraguayan medical men and a priest. At Villa Concepcion about the same time a number of suspicious deaths occurred certified either as gastric fever, typhoid fever, or typhus fever; they developed pneumonia and also had buboes. In Peru plague was widely prevalent during the year, ten departments being affected, of which Libertad suffered most. There are grounds for believing that the ravages of plague in Peru have been far worse than are shown in the official returns. The appearance of the disease in a number of places in Chili was reported, including, among others, the towns of Iquique, Pisagua, and Arica. One of the States in which plague was epidemic in 1911 was Ecuador, the capital of which is Guayaquil, where, up to August, about 650 cases had been notified; other places in Ecuador attacked by plague during the year were Babahoyo, Milagro, and Duran. Venezuela was also invaded, cases being reported at Caracas, Santa Rosalia, and Baruta; information from this State is always difficult to obtain, but it is asserted, apparently on good authority, that the disease was very prevalent, though the fact was purposely concealed by the officials at Caracas. A single case imported from Guayaquil was reported in the Panama Canal Zone in October.

In the island of Trinidad a few plague cases came under notice in the early part of 1911. For some years there has existed an epizootic of plague among the ground squirrels over a wide area in California in the United States. Week by week cases are reported, particularly in Contra Costa county, among these rodents by the officials engaged in searching for them; but only three human cases of plague were notified during the year in that State. In each of these instances it is believed that the infection was derived from ground squirrels. At Seattle, in the State of Washington, where plague was prevalent some years ago, three infected rats were discovered in August and September, the last infected rodent previous to this having been reported in February, 1910.

Plague in Europe.

In Russian Europe, at Odessa, the outbreak of 1910 was continued by a number of scattered cases throughout 1911, and in the province of Astrachan, where there is an endemic centre of plague in the Kirghiz Steppes, the disease was reported though in no great amount. During the year a commission, comprising Professor E. METCHNIKOFF, Dr. A. T. SALIMBINI, Dr. E. BURNET, and Dr. T. JAMANUCHI, has been investigating plague, as it continued to appear in the Kirghiz Steppes. The endemicity of the disease in that region is believed to be associated with a species of marmot smaller in size than the tarabagan which is found in Siberia, Mongolia, and Manchuria. A ship from Odessa landed a single case at the lazaret at Doel in the port of Antwerp. A single case was also reported at Glasgow on a vessel which had come from the port of Karachi. At Shotley, in East Suffolk, in October, an isolated case of plague was discovered, and in the country around, which was systematically searched for infected rats; a few plague-stricken animals were found among the many thousands examined by experts. Some infected rats were found at Wapping in the port of London in June, but none since then. At Lisbon a suspected case of plague was mentioned by the Spanish Consul on the bills of health, but the Lisbon authorities denied that any such case had occurred.

Plague in Africa.

Plague is now regarded as being endemic in Egypt, notwithstanding the well-directed efforts of the Egyptian Public Health Department. During 1911 up to the beginning of October over 1600 cases had been notified, and of these about 1000 proved fatal. Of the 13 provinces invaded by the disease the largest number of cases were referred to Keneh and Assouan, in each of which about 500 attacks were certified. Among the towns affected Alexandria had 52 cases, and Port Said 41 in the same period. A few cases were reported also in Cairo and Ismailia. In Algeria some persons were attacked by plague in Philippeville during November. In the hinterland of Mazagan in Southern Morocco, over an area of more than 1000 square miles, plague raged from the middle of 1910 till the autumn of 1911. It is estimated that at least 10,000 deaths were caused by the epidemic, more women than men being attacked; the reason assigned for this is the fact that females remain in their tents or houses most of the day and are therefore more liable than men to be bitten by infected fleas. The districts invaded were mostly in the Dukali province, but the epidemic extended also to the hinterland of Saffi and Mogador. The infection is supposed to have been introduced by a caravan from the south. Plague was reported in British East Africa at Nairobi, Kisumu, and Port Florence; also in German and Portuguese East Africa as well as at Zanzibar, though not in any great amount. Mauritius had its annual epidemic, which was, however, smaller than usual, only about 200 cases, the majority of them at Port Louis, being notified.

Plague in the Near East.

In Persia plague was prevalent in the port of Bushire; some ship-borne cases also occurred at the lazaret of Lingah, the patients having been brought across the Persian Gulf from Debai, which is on the opposite coast of Arabia. The Bahrein Islands suffered severely, for in about three months no fewer than 1750 persons died from plague in Manana and other places on these islands. The disease occurred also along the Arabian shore of the Persian Gulf in a number

of localities, including Mascat; and cases were likewise reported at Basra. Plague appeared in the port of Jeddah in the Red Sea early in the year but did not become acutely epidemic. The occurrence of the disease was also notified at Beirut, Adalia, and Smyrna, including the lazaret of Clazomenes, some of the instances being ship-borne.

Yellow Fever in South America and the West Indies.

In 1911, as in former years, the chief localities affected by yellow fever were situated in South and Central America, the West Indies, and the West coast of Africa. In Brazil the place that suffered most was Manaos, where the disease is endemic, and where up to October more than 200 persons had lost their lives from this malady. Cases also occurred on board two ships shortly after their departure from the port of Manaos for Liverpool. Para, too, experienced its annual outbreak of yellow fever during the year, and among other places in Brazil in which the disease was reported in 1911 were Bahia, Ceara, Marcos, and Pernambuco.

At Rio de Janeiro, where formerly yellow fever was very prevalent year by year, and where, since the carrying out of important sanitary works and the institution of anti-stegomyia measures, the disease had completely disappeared, three cases were notified in 1911, one of them imported from Bahia. Unfortunately, the funds which should have been expended on the anti-stegomyia measures and other preventive work have been largely diverted during 1910 and 1911 to other purposes, and fear is now expressed by thoughtful observers that yellow fever is likely to return to Rio de Janeiro. It has even been asserted that this has already occurred, and that deaths from yellow fever have recently been certified in Rio de Janeiro as due to the "grippe," the mortality from which has arisen in a very marked manner both in 1910 and 1911. Whether this be true or not, it is undeniable that following the relaxation of the measures a great increase in the number of stegomyia has been observed in the city, and this itself may be regarded as ominous.

Another South American State which suffered somewhat severely from yellow fever in 1911 was Ecuador, the majority of the cases being referred to Guayaquil, the capital of the country. Among 220 cases reported in this city 14 were notified on board a coaling vessel in the docks. Among other places in Ecuador in which yellow fever was present during 1911 may be mentioned Milagro, Naranjito, Yaguachi, Calaroma, Bobohoya, Bucay, Duran, and San Antonio. In Venezuela there was an outbreak at Caracas, the capital of the State, cases being also notified at La Guaira, La Pastora, Mayquetia, and San Juan. In Honduras the presence of the disease was suspected at Puerto Cortez, but there was no definite confirmation of the diagnosis.

In Mexico, after a complete absence of the disease of some months' duration, yellow fever reappeared in August at Merida in the province of Yucatan, where up to the end of October more than 40 cases had been reported. It has been suggested that this recrudescence might have been connected with an influx of non-immunes into the locality owing to the operations of the Mexican revolutionaries and the subsequent presence of the military brought from distant districts where yellow fever is not endemic. It is understood than an official investigation into the outbreak is being made by Dr. C. M. GARCIA on behalf of the Mexican Government. Other localities in which cases appeared in Mexico during 1911 included Frontera and Salina Cruz; at the latter place the infection was stated to have been brought from Guatemala, where, however, there is no official mention of the occurrence of the disease. At Bogota, in the State of Colombia, an epidemic, suspected to be yellow fever, was reported during the year, but no confirmation of the diagnosis has been officially announced. At Victoria, in Grenada, and at Bridgetown, in Barbados sporadic cases of yellow fever were certified.

Yellow Fever in West Africa and Elsewhere.

On the west coast of Africa, in the first half of 1911, scattered cases of yellow fever were notified, some of them in May at Accra in the Gold Coast Colony, others at Bathurst in the Gambia Colony from May to July. A fatal case occurred on a ship from Bathurst bound for a French port and the body was buried at sea. The presence of yellow fever at Sierra Leone in April was also reported. At Bissao and at Boulam in Portuguese Guinea the disease was stated to be present in May and June, but no particulars of the outbreak have been as yet published. The late Sir RUBERT BOYCE, F.R.S., for some time before his death, maintained with great ability and persistence, before the Society of Tropical Medicine, as well as in his published papers, that yellow fever was endemic in West Africa; that it occurred in all its forms from a mere "embarras gastrique" to the typical black vomit; that it passed often unrecognised and was wrongly diagnosed as something else; and that the only remedy was systematic destruction of the stegomyiæ which abound in that part of Africa. His views, however, did not altogether meet with general acceptance.

In the Hawaiian Islands at Honolulu a Japanese ship arrived on Oct. 21st having on board a patient who was convalescent from yellow fever which had been contracted in Mexico. He was detained at the quarantine station, and about seven days later one of the men employed in guarding the ship in Honolulu, pending disinfection, sickened of the disease. The occurrence of yellow fever in Asia is greatly feared by some epidemiologists as likely to result from the opening of the Panama Canal in about two years' time, and such an instance as the above may, perhaps, be regarded as some confirmation of the possible extension in the near future of the disease to Japan, China, Malaya, the Dutch East Indies, Straits Settlements, Ceylon, and India unless care be taken to prevent infective stegomyiæ hiding themselves on board ships and travelling to Asiatic ports. As far back as 1903 this particular danger likely to arise in connexion with the opening of the Panama Canal was pointed out by Sir PATRICK MANSON in a paper read before the London Epidemiological Society. In order, however, to investigate this danger and study means of prevention Major S. P. JAMES, I.M.S., is visiting the endemic areas of infection.

The Alleged Specific Organism of Yellow Fever.

In the early part of 1911 a yellow fever bureau was founded in connexion with the Liverpool School of Tropical Medicine, and in association with it a monthly bulletin, as has already been stated, was started in May, the late Sir RUBERT BOYCE, F.R.S., being appointed its editor. His much regretted and untimely death in June, just after the first issue of the Bulletin, necessitated the appointment of a new editor, and Dr. HAROLD SEIDELIN was chosen. This new bureau undertakes the identification of mosquitoes sent to Liverpool, and it also carries out the examination of blood smears and tissues.

Search continues to be made for the specific organism of yellow fever, and some evidence has been brought forward in support of the claim made by Dr. SEIDELIN that the protozoon-like bodies found by him in the blood and tissues of patients are the actual organisms which cause the disease. It is worth mentioning that during the recent yellow fever outbreak in Mexico at Merida, to which allusion has already been made, two local medical men, Dr. DIEGO HERNANDEZ and Dr. HIRCANO AYUSO, both of whom were formerly assistants to Dr. SEIDELIN when he was professor of pathology at Merida, have sent specimens of blood smears and portions of tissue to the bureau for examination, and that in the smears in nearly every instance the "yellow

fever bodies" were found. Dr. HERNANDEZ also reports that he found the same "bodies" in blood smears taken from patients under his care, in which there had been doubt as to the diagnosis, the finding of the "bodies" enabling him at once to make a positive diagnosis. If this be confirmed by independent observations the results must prove of the greatest value. In view of the importance of the subject, the Liverpool School of Tropical Medicine has despatched Dr. SEIDELIN to Mexico to make use of the opportunities afforded by the epidemic at Merida in furthering the identification of the specific organisms of yellow fever. He sailed on Dec. 9th.

The Paris International Sanitary Conference of 1911 on Cholera, Plague, and Yellow Fever.

The International Sanitary Conference, which was originally planned to meet at Paris in April last, and to which the delegates had been summoned to assemble in October, did not meet, owing to various reasons, including the cholera epidemic in Italy and elsewhere, until the middle of November. The Conference was called to decide what changes, if any, should be made in the existing convention, which was agreed to at Paris in 1903. Fears were expressed by some persons in this country that the more timid representatives from some other countries would seek to increase the restrictions placed upon shipping, and thus impose further burdens upon British trade and commerce. We trust these fears will not be realised. It is not, we understand, likely that the decisions of the Conference will be available for publication for some time.

The British delegates nominated to the Conference were: the Hon. L. D. CARNEGIE, Minister Plenipotentiary, Councillor of the British Embassy at Paris; Dr. THEODORE THOMSON, C.M.G., Assistant Medical Officer, Local Government Board; Dr. F. G. CLEMOW, British Delegate on the Constantinople Board of Health; Dr. A. A. MORRISON, British Representative on the Egyptian International Quarantine Board; and Dr. R. W. JOHNSTONE, Medical Inspector to the Local Government Board. Mr. O. G. SARGEANT, of the British Embassy at Paris, acted as secretary for the English delegation. Surgeon-General Sir BENJAMIN FRANKLIN, K.C.I.E., I.M.S. (retired), represented the Government of India. The Egyptian delegates were ISMAIL PACHA SIDKI, Under-Secretary of State to the Ministry of the Interior, and Dr. M. A. RUFFER, C.M.G., President of the Egyptian International Quarantine Board. The following European countries were represented at the Conference—viz., France, England, Germany, Holland, Austria-Hungary, Belgium, Bulgaria, Denmark, Sweden, Norway, Russia, Servia, Turkey, Portugal, Spain, Roumania, Switzerland, Luxemburg, Italy, and Greece. The Western hemisphere sent delegates from the United States, Argentina, Brazil, Bolivia, Chili, Costa Rica, Cuba, Ecuador, Guatemala, Haiti, Honduras, Mexico, Panama, Paraguay, Salvador, and Uruguay. Asia sent representatives from India, Persia, Siam, and China.

Owing to the importance which bacteriology has assumed of late years in the diagnosis of plague and cholera, the Conference at one of its early meetings appointed a Bacteriological Commission to consider a number of points in connexion with this important branch of the subject. This commission comprised the following experts: Dr. RUFFER (Egypt), Professor G. GAFFKY (Germany), Dr. A. CALMETTE (France), Dr. H. D. GEDDINGS (United States of America), Dr. F. MURILLO (Spain), and Dr. A. PRAUM (Luxemburg), with Dr. H. POTTEVIN, of the International Health Bureau, as secretary and reporter. We learn with regret that owing to illness Dr. THEODORE THOMSON was unable to proceed to Paris to act as one of the British delegates at the Conference.

Small-pox on the Continent of Europe.

Russia was the country which suffered most from small-pox on the continent of Europe during 1911, the disease being epidemic in many towns and districts, including St. Petersburg, Moscow, Warsaw, Odessa, Riga, and Libau, and was also epidemic in Vladivostock. In Austria-Hungary the occurrence of small-pox was reported in the provinces of Bohemia, Galicia, and Carinthia, as well as at the port of Trieste. There were outbreaks in Turkey, at Beirut, Kharput, and other places; and in Greece the disease occurred at Athens and in the adjoining districts, as also in the Island of Corfu. A few attacks were notified in Malta. In Italy there were serious epidemics, more particularly at Palermo and Naples; while smaller outbreaks were reported from Genoa, Turin, and other places. The prevalence of small-pox in Spain, to which reference was made in 1910, was continued during 1911, the chief towns affected being Madrid, Barcelona, Valladolid, Seville, Santandar, Valencia, and Malaga. Some cases also occurred in Gibraltar, while in Portugal there was a sharp epidemic at Lisbon. Little information is obtainable as to epidemics in France, but it is known that over 100 cases of small-pox occurred in Paris, and a considerable number in Marseilles. Early in the year there was an outbreak of the disease in the Swiss cantons of Argau, Bern, and Basel. Although Germany is a well-vaccinated country, and though anti-vaccination has not as yet made much progress among its people, notwithstanding the noisy demonstrations of a few fanatics, it is unable to prevent the importation of the infection from time to time across its frontiers from the unvaccinated neighbouring states, and particularly from Russia. In 1911 up to the beginning of November 183 cases had been notified in Germany, of which 88 were foreigners, mostly Russians. Only a few attacks were notified in Holland at Rotterdam; and in Belgium at Antwerp.

So far as can be discovered there was no small-pox during 1911 in the well-vaccinated countries of Denmark, Norway, and Sweden, in which in past years little has been heard of the disease beyond occasional imported ship-borne cases which were easily dealt with.

Small-pox in Africa and the Near East.

In Egypt small-pox was somewhat widely epidemic, and up to September more than 2200 cases had been reported with 617 deaths, giving a case mortality-rate of 27·9 per cent. The chief Egyptian towns affected were Cairo, Alexandria, and Port Said. The disease was prevalent in Algeria, especially at Constantine, and some cases occurred in the town of Algiers. There was also an epidemic in Morocco, and some cases were reported at Tangier. The West African Colony of Gambia experienced a localised outbreak at Bathurst lasting from April to June. In Cape Colony in the Herschel district, and in the Transvaal at Johannesburg, as also at some places in the Orange Free State, the occurrence of small-pox was certified during the year, and some cases came under observation in East Africa at Lorenzo Marques. The epidemic, which had begun in 1910 at Zanzibar, continued during part of 1911; and in the same way the prevalence of small-pox observed in Abyssinia and Berbera in the previous year persisted in the early months of 1911. At several places in Arabia small-pox appeared, and a sharp outbreak was referred to Aden, where up to July as many as 330 cases had been treated.

Small-pox in Asia and Oceania.

Small-pox was very prevalent in many of the Indian provinces during 1911, and epidemics occurred in a number of cities, including Madras, Bombay, Karachi, Rangoon, and Moulmein. In Ceylon an outbreak was reported at Colombo, and in the Straits Settlements at Singapore and Penang. There was an epidemic of small-pox at Bangkok,

the capital of Siam, as also at the seaport town of Saigon in Indo-China. In many towns and districts in the Chinese empire small-pox occurred in epidemic form, and among other places outbreaks were reported at Hong-Kong, Shanghai, Hankow, Nanking, Chunking, Tientsin, Swatow, and Amoy. Some cases were notified in Japan at Kobe and in other towns, as also in the island of Formosa. The disease was also reported to have occurred in the Dutch East Indies, particularly at Batavia. Small-pox was prevalent in the Philippine Islands during the first half of 1911, and some cases came under observation at Honolulu, Hilo, and other places in the Hawaiian Islands.

Small-pox in America.

In the United States small-pox was widely prevalent, but continued to be, as of late years, of an extremely mild form. Up to November over 21,000 cases were notified, with only about 100 deaths. The States which suffered most included North Carolina, Florida, Kansas, Colorado, Utah, and Oklahoma. In Canada the disease was spread over a wide area, the provinces that were the worse sufferers being Quebec, Prince Edward Island, and British Columbia. In Quebec, though the cases numbered some thousands, the mortality was very small, the type being the same as that met with in the United States.

In South and Central America the disease was present in many localities in a more virulent form. In Brazil there were some epidemics, especially at Pernambuco, where nearly 650 deaths were reported in seven months, and cases also occurred in Rio de Janeiro, Para, and Bahia. A suggestion has been made by Dr. ZEFERINO MEIRELLES that small-pox may be spread in Brazilian towns by the agency of fleas. In Argentina the disease was epidemic in Buenos Aires and Rosario, more than 250 fatal cases occurring in the latter city in six months, and in Uruguay at Montevideo. Small-pox continued to be prevalent in Chili at Valparaiso, and raged in a very virulent form in the province of Coquimbo. The presence of the disease at Salaverry, Truxillo, and elsewhere in Peru was reported during the year. Cases were notified in Ecuador at Guayaquil; in Colombo at Carthagena; in Guatemala at Estoria and Guirgua; and in British Guiana at Georgetown. Small-pox was widely diffused over Mexico during 1911, and outbreaks were reported, among other places, at Tampico, San Luis Potosi, the city of Mexico, Aguascallientes, Inuris, Juarez, Mazatlan, Tulcahana, and at San Juan Bautista, the capital of the province of Tabasco. So far as is known, small-pox was absent from the West Indies during the year, save that a single case, imported from Rio de Janeiro, was notified at Bridgetown in the island of Barbados.

FORENSIC MEDICINE.

ACTS OF PARLIAMENT.

Mr. LLOYD GEORGE'S measure of National Insurance has occupied the attention of the Legislature and the public with questions of vital importance to the medical profession during the past year, and has been fully discussed in these columns. The Bill was read for a third time in the House of Commons on Dec. 6th and in the House of Lords on Dec. 15th.

Among other legislation achieved during the earlier part of the year, and in most cases of indirect rather than of direct interest to the medical profession, may be mentioned 1 & 2 Geo. V. Ch. 6, to be cited as the Perjury Act, 1911. This deals with other offences of untruthfulness besides false statements made on oath in judicial proceedings and in other matters, for it codifies and consolidates the law with reference to statements made not on oath but in matters of public importance, where, for example, an Act of Parliament orders answers to be made to questions and information to be supplied for the purpose of making the statute in question effective. To speak generally, it repeals existing statutes or sections and imposes penalties which take the place of pre-existing ones. Notably it repeals section 39 of the Medical Act, 1858. The offence of obtaining or seeking to obtain registration by means of false representations now comes under a general section (section 6) in the new Act relating to all public registers or rolls kept in pursuance of Acts of Parliament. Section 4 of the Act deals expressly with false statements and answers made in connexion with the registration of births and deaths, parts of the Registration Act, 1874, being repealed with necessary alterations in the corresponding Act of 1880 for Ireland. Section 2 of the Midwives Act (for the punishment of midwives seeking to obtain enrolment by means of false declarations or certificates) is also repealed, and the declarations made under the Cremation Act of the same year (1902) are also apparently brought under the new law.

1 & 2 Geo. V. Ch. 5, The Geneva Convention Act, 1911, prohibits the use of the emblem of a red cross on a white ground or the words "Red Cross" or "Geneva Cross" by "any person for the purposes of his trade or for any purpose whatsoever" without the authority of the Army Council, providing penalties for breaches of the law in this respect. Existing trade-marks which would otherwise be illegal are to be allowed to be used for four years from the passing of the Act (August 11th, 1911).

1 & 2 Geo. V. Ch. 21, Factory and Workshops (Cotton Cloth Factories) Act, 1911, empowers the Home Secretary to make regulations for the protection of health in cotton factories.

1 & 2 Geo. V. Ch. 27, Protection of Animals Act, 1911, repeals several existing Acts or parts of Acts relating to cruelty to animals and kindred subjects, and codifies the law relating to this subject, increasing substantially the penalties which magistrates may inflict for cruelty. Acts lawfully done under 39 & 40 Vict. Ch. 77, the statute which regulates experiments upon animals for scientific purposes, are expressly exempted from the operation of this new law.

The Copyright Act, 1911, confers important advantages upon the authors of books and upon artists, which medical men will share with their fellow citizens.

REGULATIONS AS TO THE SALE OF POISONS.

New regulations were issued by the Privy Council under Section 5 of the Poisons and Pharmacy Act, 1908, and came into force on Oct. 1st. One affects the sale of all substances to which the section applies, and orders the additional words "not to be taken" to be printed distinctly on the box, bottle, wrapper, vessel, or cover in which the substance is contained; and another obliges the delivery of liquid substances in bottles or containers distinguishable by touch. Both refer to sale by retail.

WORKMEN'S COMPENSATION ACT, 1906.

For the sake of convenience cases of medical interest connected with workmen's compensation are here grouped together, whether appeals to the House of Lords or Court of Appeal, or the decisions of county court judges upon the questions of law and fact as to which they are arbitrators. The enormous increase in litigation for which medical evidence is essential, due to the law of workmen's compensation, is strikingly illustrated.

IN THE HOUSE OF LORDS.

Morgan v. *William Dixon, Limited.*—This was a Scottish case. The applicant, a workman, claimed compensation for alleged injuries by an accident, and the employers required him to submit himself for examination by their medical man. The workman expressed himself willing to do this, but stipulated that his own medical attendant should be present

at the examination. The employers refused to accede to this and applied to the Sheriff Substitute, contending that the workman had refused to submit to examination and that his claim should be sisted. The Sheriff Substitute adopted this view and the application for compensation was sisted accordingly, the Second Division of the Court of Session on appeal upholding the decision of the Sheriff Substitute. The case accordingly, on further appeal by the workman, came before the House of Lords, when the Lord Chancellor, Lord ATKINSON, and Lord GORELL (Lord SHAW dissenting) upheld the decision of the Court of Session. The House of Lords declined to formulate a rule of law that as an abstract unconditional right the workman might have his medical adviser present when examined on behalf of the employers. Whether it might be a reasonable condition for the workman to impose was a question of fact for the arbitrator to decide. He might decide that it was a reasonable condition or not, as a matter of fact; but the House of Lords did not decide as to facts, they laid down as a matter of law that there was no absolute right in the workman to insist on the presence of his own medical adviser. This and the two following cases, decided earlier in the year, throw light upon important points which arise under Schedule I., section 4, of the Workmen's Compensation Act.

IN THE COURT OF APPEAL.

Warby v. *Plaistowe and Co.*—The applicant, a workman receiving weekly compensation after being injured in an accident, was required by his employers to submit himself to examination by their medical man, Dr. R. J. COLLIE, either at the house of Dr. COLLIE, in Porchester-terrace, Bayswater, or at the workman's house, Eden-grove, Holloway. The workman, on the advice of his solicitors, refused to be examined except at their office and in the presence of a member of their firm. The employers, treating this as a refusal to submit to medical examination, discontinued their weekly payments to the workman, who applied to the county court judge asking him to order their continuance. The county court judge took into consideration all the facts of the case, including allegations against Dr. COLLIE that his conduct towards workmen examined by him was such as to justify the imposing of the above conditions, and held that even supposing these allegations to be true the conditions proposed would not protect the workman more efficiently than the presence of his own medical adviser. He further expressed himself satisfied that the allegations against Dr. COLLIE were not true, and held that on either assumption the conditions sought to be imposed were not reasonable, and that therefore there was a refusal on the part of the workman to submit himself to examination, and that the workman's application to have his weekly payments renewed must fail. The workman appealed, and the Court of Appeal upheld this decision, expressing disapproval of a solicitor's office for such examinations and of the imposing of conditions upon the employers by the workman's solicitors. The court pointed out that the Workmen's Compensation Act gave the employers the right to select their own medical man, and gave no right to the workman to impose conditions.

Harding v. *Royal Mail Steam Packet Company.*—The applicant, a workman receiving weekly compensation after being injured in an accident, was required by his employers to submit himself to examination by their medical man, Dr. R. J. COLLIE, at his house in Porchester-terrace, Bayswater. The workman refused to submit to examination except at the office of his solicitors in the City or at the surgery of his own medical attendant. The county court judge held that this did not amount to a refusal to submit to medical examination so as to justify discontinuance of weekly payments by the employers. The Court of Appeal upheld this decision, the Master of the Rolls saying that the question to be decided was one of fact: "Was the refusal to go to the employers' doctor's surgery so unreasonable as to amount to a refusal to submit to examination or to be obstruction?"

Hawkins v. *Powell's Tillery Steam Coal Company.*—An elderly man engaged in a colliery helped to handle some trucks and afterwards did other work. While engaged on the second work he became ill and died shortly afterwards at home, post-mortem examination showing that death was probably due to angina pectoris. The county court judge came to the conclusion that death was due to over-exertion in pushing the trucks. The Court of Appeal held that there was no evidence to support the finding of the county court judge, and the appeal of the employers was allowed. The court distinguished this case from Glover, Clayton, and Co., Limited, *v.* Hughes (1910, A.C. 242) (the case of a man who died from an aneurysm while tightening a nut with a spanner), laying down that it must be established by direct evidence or legitimate inference from proved facts that death arose out of, as well as in the course of, the employment.

Warner v. *Couchman.*—A journeyman baker, whose right hand and arm had been injured by frost-bite while he was delivering bread, claimed compensation for an injury arising out of his employment. The county court judge refused compensation and the Court of Appeal upheld this view, being of opinion that there was no special danger affecting the claimant beyond what other drivers and persons working out of doors encountered, and that consequently his injuries did not arise out of his employment. From this Lord Justice FLETCHER MOULTON dissented.

Ball v. *William Hunt and Sons, Limited.*—A workman, who had long lost the sight of his left eye, met with an accident which made it necessary to remove the eyeball, and claimed compensation on the ground that his pre-existing blindness in one eye being made manifest deprived him of the power to obtain work. The county court judge held that the applicant was not incapacitated by the accident, and the Court of Appeal upheld this view, holding that the accident which only made apparent the pre-existing incapacity did not entitle the claimant to compensation. From this judgment Lord Justice FLETCHER MOULTON dissented.

Carolan v. *Harrington and Son.*—In this case a county court judge had had to deal with a case where a workman was dead and where there was considerable conflict of medical evidence as to whether death was due to an accident which had in fact befallen the deceased. He accordingly referred the question to a medical referee, who decided against the applicants for compensation. They appealed on the ground that upon the construction of the Workmen's Compensation Act and Regulations the medical referee could only be resorted to when the workman was alive and not when he was dead. The Court of Appeal held that the judge's power to refer the case to a medical referee under Schedule II., par. 15, of the Act extends to a case where death has occurred as the alleged result of an accident.

Roles v. *Pascall and Sons.*—A workman met with an accident in July, 1909, but did not enter a hospital for treatment for the injuries then sustained until April, 1910. In July, 1910, he claimed compensation under the Workmen's Compensation Act, 1906, having only become aware of the existence of the Act and of his having probably the right to compensation when in the hospital. Consequently, he had exceeded the time allowed by claiming more than six months after the occurrence of the accident. The county court judge held that there was "reasonable cause" within the meaning of the Act for the failure to give notice in time, but the Court of Appeal held that the workman's ignorance of the law was neither a "mistake" nor "reasonable cause"

either of which might have entitled him to be excused in respect of the delay.

Proctor and Sons v. *Robinson, and Cardiff Corporation* v. *Hall.*—Two cases argued in the Court of Appeal were concerned with the question of discontinuing an award of compensation to a workman to the extent justified by his capacity to do light work. In HALL'S case a medical referee had reported him "quite able to do any form of light work, more particularly such as would require principally the use of the right hand." It was held by the court of appeal that this was a finding of capacity for work such as that described, and that the fact that the man had tried to obtain light work and failed did not affect the question. In ROBINSON'S case the county court judge, after some conflicting medical evidence as to the man's incapacity, decided that he could do light work if he could get it, but made no order to reduce the compensation as no evidence was before him that such light work as the man could do was obtainable. The Court of Appeal upheld this decision, laying down that it was for the employers to show what kind of light work the workman could do, and that there was some chance of his obtaining it.

Claim by a House Surgeon.—The house surgeon of a charitable institution, to which an X ray apparatus had been presented, voluntarily offered his arm for the testing of the length of exposure to the rays, and having sustained a burn claimed against the infirmary committee under the Workmen's Compensation Act. The county court judge, whose decision was afterwards upheld by the Court of Appeal, held that the claimant was not entitled to compensation on the ground that it was no part of his duties to offer himself for experiments, and that consequently the accident did not arise out of and in the course of his employment.

IN THE COUNTY COURT.

Scarlet Fever as an Accident.—In the Manchester county court an award was made in favour of a workman as for an accident in respect of infection with scarlet fever, the claimant being a mortuary porter whose duty it was to clean the mortuary at the Monsall Fever Hospital. The county court judge found that the disease was contracted in the mortuary and that it amounted to an accident within the meaning of the Act.

IN THE DIVISIONAL COURT.

Pharmaceutical Society v. *Jacks.*—A defendant, not being a registered pharmaceutical chemist but a tradesman licensed to sell poisonous substances for agricultural and horticultural purposes, sold a bottle containing a poisonous compound without complying with the regulations for such sales in that he had not labelled the bottle with his name and address. The Pharmaceutical Society sued the defendant for a penalty under section 15 of the Pharmacy Act, 1868. The county court judge held that the proper course would have been to report the defendant to the local authority which licensed him, or to prosecute him under section 17 of the Act of 1868 for the offence of selling a poison without a label, and gave judgment for the defendant. The divisional court held that the defendant might be sued for a penalty by the Pharmaceutical Society under section 15, and none the less so because the facts showed that he had also committed an offence under section 17.

Dodd v. *Pearson.*—Section 253 of the Public Health Act, 1875, provides that except in certain cases for which express provision is made proceedings for the recovery of a penalty shall not be taken by any person other than the local authority or the person aggrieved without the consent of the Attorney-General. A district council refused to prosecute in a case relating to diseased meat, and the police took the matter up and secured a conviction. The meat had been destroyed without reaching the public, so there was no person aggrieved. As the police had not obtained the Attorney-General's consent and were not persons aggrieved the Divisional Court held that the conviction could not stand.

IN THE HIGH COURT.

Thomas v. *Barker.*—Before Mr. Justice DARLING and a special jury an action brought against Mr. H. A. BARKER, carrying on business as a "bone-setter," had as its result a verdict for the plaintiff for 20 guineas damages. Mr. THOMAS had sustained an injury to his knee ten years before his treatment by the defendant from which he had not recovered, and before he went to Mr. BARKER it was the seat of tubercle. The defendant caused gas to be administered, and on two occasions, according to the plaintiff's case, moved the joint to an extent and in a manner which were matters of dispute at the trial. Subsequently to the treatment by Mr. BARKER amputation of the limb had to be performed, and the action was based upon the allegation that the conduct of the defendant in treating a tuberculous joint as described was responsible for this result. Judgment was given for the above-mentioned amount with costs on the High Court scale and a certificate for a special jury.

Action Against a School.—An action was brought against the governors, the headmaster, and a housemaster of Sherborne School on behalf of a boy on the ground that through negligent treatment of a whitlow at the school he had lost his arm. The whitlow, which was on the thumb, was treated by the school medical officer and matron and disappeared in a few days, but after the boy returned home septic poisoning, followed by necrosis, necessitated the amputation of the right arm, and a micro-organism common in whitlows was found in the pus. Medical evidence on both sides was given, that for the defence ascribing the disease in the right arm to the presence of the micro-organism which caused the whitlow, but not to the whitlow or to any neglect in treating it. A verdict was found for the defendants, with which the Lord Chief Justice expressed his full concurrence.

Corbin v. *Stewart.*—Mr. Justice SCRUTTON, sitting without a jury, tried a case in which the value of a medical practice sold by the plaintiff to the defendant was an issue in dispute, and also whether a contract to introduce to patients had been properly carried out. A point of law was raised as to whether the plaintiff, the widow of a medical man, could dispose of the goodwill and receive payment for it. A counterclaim by the defendant for medical attendance on the plaintiff's children was also met by a defence alleging a binding custom to treat the families of medical men without charge. The judge held that the plaintiff could sell the right to carry on the practice of the deceased in the same house, as it belonged to her, and that she could contract as she had done to introduce him to the practice, but suggested that the estate might have a claim against her for money received in respect of the latter part of the transaction. On the question of medical attendance on the plaintiff's family, he held that it was not necessary to establish the existence of a binding custom: it was enough to prove a general practice, which had been done. If the defendant did not intend to conform to that practice he should have informed the widow at the outset, who might then have sought medical attendance from another practitioner. Judgment was given for the plaintiff on claim and counterclaim.

Actions Arising out of Nuisances.—Among actions for nuisances which succeeded may be mentioned one brought in the Chancery Division by the Plymouth corporation against the Plymouth Fish Guano and Oil Company, to restrain the defendants from carrying on their manufacture of fish guano and manures from fish offal and refuse so as to cause a nuisance. An injunction was granted. Another action was also successfully brought in the Chancery

Division by Mr. H. O. BECKER, an artist, who obtained an injunction and £25 damages against Earl's Court Exhibition, Limited, in respect of a nuisance caused to him and his family in their home near the Earl's Court Exhibition, by the noise of certain side-shows and other noises in connexion with amusements at the exhibition.

Rayner v. *Corporation of Stepney.*—In the Chancery Division an injunction was obtained against a local authority restraining them from enforcing a closing order in respect of certain insanitary dwellings under the Housing, Town Planning, &c , Act, 1909, on the ground that the prescribed form had not been followed in the order served upon the owner. The statutory form has at the foot a note setting out the section of the Act which gives an owner the right of appeal to the Local Government Board, and this had been omitted.

Browning v. *Browning.*—In the Divorce Court the President laid down, after reviewing a number of earlier decisions tending to the contrary doctrine, that the wife establishes a *prima facie* case of cruelty when she proves that her husband has communicated to her a venereal disease, and that the burden would then lie upon him to prove that he was innocent, or ignorant, or otherwise not guilty of the legal cruelty charged against him.

IN THE COUNTY COURTS.

Action against the Medical Officer of an Isolation Hospital.—An action was brought in the Hanley county court against Dr. C. H. PHILLIPS, medical superintendent to the Stoke-on-Trent and Stoke Rural Joint Hospital Board, by the father of a boy treated for scarlet fever in the Bucknall Infectious Diseases Hospital and the Bagnall Convalescent Hospital. The patient had been kept in the hospital after recovery in other respects owing to a slight sore inside the nose, and when removed by his parents was taken away in a taxicab. He afterwards developed scarlet fever again and his father also suffered from it. The medical officer was sued for alleged negligence in discharging the boy, upon whom his mother found some slight desquamation proceeding after the father had developed the disease. The case for the defence was to the effect that through the removal in a taxicab catarrh of the nostrils afterwards observed might have been brought on, and that fresh infectivity might have been the result. Evidence as to the precautions taken before discharge was given, and the county court judge, who tried the case without a jury, having found that there had been no negligence, gave judgment for the defendant.

IN THE CORONERS' COURTS.

Urgent Operations in Hospitals.—At an inquest at Southwark the evidence showed that a little boy had died in Guy's Hospital after being run over and after an operation to which assent had been refused by the father. Assent was given later, but there was delay in rendering aid recommended by the surgeons of the hospital. The matter was discussed at the inquest and a suggestion made that in such cases a committee of surgeons should be empowered to decide upon an operation and to have it performed either without parental consent or in the teeth of parental opposition. It was pointed out in THE LANCET that an urgent operation to save life must be performed, without waiting for parents to be consulted, upon the responsibility of the surgeon, and that the Children Act, 1908, already renders it punishable in a parent not to provide medical aid for his child, although he can apparently decline to allow that aid to be effective by refusing consent to an operation.

Inquest following a case of "Healing" by "Christian Science."—In the Chelsea coroner's court an inquest was held upon the body of Miss NORA BOHM (the daughter of a Norwegian gentleman) who had suffered from disease of the heart, and had at one time had medical advice with regard to it. She had been recommended by a friend to try "Christian Science," and was attended by a female "healer," who offered prayers daily, and who one evening found her patient dead. The verdict was in accordance with medical evidence based on post-mortem examination that death was due to heart disease and accelerated by dilatation of the stomach, the opinion being expressed by Dr. B. H. SPILSBURY, who made the examination, that suitable care and diet might have prolonged life for a short time.

Death from Drinking Carbolic Acid.—At an inquest upon a young stockbroker who had died from carbolic acid poisoning it was proved that he with four other persons went on board a French vessel in the Thames and was invited to drink port wine by the captain, who, by mistake, brought out a bottle of carbolic acid supplied to his ship for disinfecting purposes. Glasses were filled and a toast was drunk simultaneously by those present, with the result that five were rendered extremely ill, of whom one, the subject of the inquest, died.

A Mysterious Burning Fatality.—An inquest was held at Marlborough upon the body of a little girl who was observed to be in flames immediately after the passing of a motor-car, which had been backed out of a garage near her. It was suggested that a spark from the exhaust caused the fire and the incident was "reconstructed," with negative results, an open verdict being returned so far as the cause of the ignition of the child's clothing was concerned.

An Alleged Murderous Assault Disproved.—A maiden lady, aged 54 years, left alone in her flat, was found by her servant lying on the floor with cuts on her head, and verbally and in writing to her medical attendant, told a story of having been murderously assaulted by two men, whom she described. She became very ill and died. At the inquest the police were unable to bring forward corroborative evidence of the above story. There was evidence that no men could have reached the flat as alleged without being observed, and relatives deposed that the deceased suffered from hallucinations. Medical evidence showed that the injuries were consistent with a fall, and that death was due to heart failure and accelerated by alcoholism. The jury found a verdict accordingly, ignoring the story of an assault.

ANATOMY.

It is becoming more and more manifest every year that anatomical research and progress are becoming specialised along two quite distinct paths. The study of the developing embryo by the modern methods of wax-plate reconstruction is claiming an increasing number of workers year by year. On the other hand, the study of the adult human body is always being undertaken afresh as new surgical procedures demand fresh knowledge, or new pathological findings necessitate a more accurate acquaintance with the normal tissues. But it must be owned that a very large measure of the new knowledge of the human body is being accumulated, not at the hands of professed anatomists, but rather as the result of the labours of pathologists and clinicians. Outside the study of the central nervous system there are but few anatomical investigations which are undertaken to-day as pure research; and the stimulus for the study of comparative anatomy called forth by the doctrines of evolution shows signs of dying down, at any rate among English anatomists. So far as the study of the human body is concerned, there is, and can be, no end to the progress of research while each of the sister subjects of the science of medicine continues to make progress, for the advances in adult human anatomy are largely indexes of new methods employed in the kindred sciences of surgery, medicine, and pathology. With such advances we will deal first.

Anatomy of the Head and Neck.

A more precise knowledge of the anatomical relations of the fifth cranial nerve has been demanded by the increasing importance and frequency of surgical procedures directed to the relief of trigeminal neuralgia. The widely-employed method of injecting the main trunks near their exits from the skull has led Professor J. SYMINGTON to reinvestigate the relations of the structures traversed by a hypodermic needle thrust inwards from the cheek for the purpose of injecting the nerves. It is at once apparent from this study that such injections should not be undertaken without an intimate knowledge of the many important structures likely to be encountered in the neighbourhood of the nerve trunks. Another piece of work which deals with normal anatomy, and is of clinical interest, is that of Mr. F. G. PARSONS on the form of the parotid gland. Professor ARTHUR THOMSON has made studies in the "filtration angle" and other structures of the globe of the eye; and Dr. S. E. WHITNALL has produced a series of papers dealing with the normal anatomy of the orbit and some of its vestigeal muscles. Dr. WHITNALL'S description of the tubercle on the malar bone, for the attachment of the ligamentous structures of the outer side of the orbit, furnishes another instance of the late appreciation by anatomists of a very fairly well-developed bony feature. Mr. J. E. S. FRAZER has continued his studies of the development of the upper respiratory passages. He has dealt especially with the pharyngeal end of Rathe's pouch, which, according to his investigations, becomes involved in the downgrowth of the nasal chambers and takes up its final position upon the hinder end of the nasal septum immediately above the palate; such a fate would well explain the occasional presence of pituitary remnants in this situation. He has also reinvestigated the formation of the primitive mouth and the development of the adult nasal chambers, and in his account of the process a large share of the formation is assigned to the maxillary processes, a finding which well accords with the adult nerve-supply of the parts.

Professor E. FAWCETT has made further contributions towards our knowledge of the development of the skull bones. His studies have been mostly concerned with the maxilla and the vomer, both of them bones the development of which is of direct importance in the study of surgical malformations of the face. Professor FAWCETT'S work rings true in that it tends to simplify the processes of development and not to complicate them, and it is satisfactory to learn that the view of CAMPER, and more lately of HUMPHRY, that the maxilla is derived from a single centre of ossification, is so definitely confirmed by these most recent researches.

Dr. J. W. JENKINSON has left the study of the morphology of the ossicles of the ear in a more definite position by his researches on their development in the mouse. He has shown that both the incus and the malleus are derivatives of the upper part of the blastema of the mandibular or first branchial arch, and that the stapes is derived from the dorsal median portion of the hyoid or second branchial arch. These conclusions he has arrived at by the study of embryos at a very early stage of development. The pituitary gland has come in for a more than usual amount of attention. Its blood-supply has been minutely studied by W. E. DANDY and EMIL GOETSCH, and its abnormal fossa in the skull has been investigated by Dr. W. L. H. DUCKWORTH in a case which showed other osseous anomalies. Acromegaly has absorbed the attention of many workers, and we may mention the papers by Professor ARTHUR KEITH which appeared in our pages.[1] Professor KEITH has made a study of the skeletal remains of many well-known acromegalic giants, among which O'BRIEN must be ranked, and he has been fortunate enough to secure for the museum of the Royal College of Surgeons of England a very remarkable series of specimens to illustrate the pathological changes which are met with not only in the bones but in the viscera of persons suffering from this strange disease.

Another important contribution to this subject has been made by Professor A. C. GEDDES, who has given a detailed account of the skeleton of a woman who had suffered from this disease for 25 years, during the greater part of which time she had been under close observation. In this study of acromegaly the anatomist has made strides into the domain of the pathologist, and all that is best in anatomy is likely to be awakened by such an excursion. Another research of practical interest in the study of the changes taking place in bone is that of Dr. DUCKWORTH on the repair of fractures as seen in the anthropoid apes. This opens up the whole subject of the natural repair processes of bones, a subject which has received a recent addition of knowledge from the findings of the anatomists engaged on the Survey of Nubia. Dr. F. WOOD JONES has drawn attention to the close relationship between the posterior divisions of the cervical nerves and the corresponding cervical vertebræ, an association which may possibly have a clinical bearing in cases of obscure neuritis affecting these cervical roots.

Anatomy of the Abdomen.

Dr. D. G. REID has made a series of studies of the peritoneal relations of the fœtus, and Professor SYMINGTON and Dr. WOOD JONES have continued investigations on the anatomy of the rectum. Dr. MAURICE GÉRARD has given a minute description of the arterial supply of the kidney, and with Dr. GEORGES has also conducted an investigation into the form and situation of the suprarenal glands. The structure of the pancreas has been exhaustively treated by Dr. GELLÉ, who has followed up his study of the diabetic pancreas by a systematic examination of the non-diabetic gland. Professor A. F. DIXON has put on record the dissection of a case of additional kidney, a rare condition, but one which, nevertheless, has at times been recognised in the course of operation. Dr. J. LEWIS BREMER has made an elaborate study of the minute structure of the tubules of the testicle and epididymis; and a contribution of more practical interest dealing with the genital organs is that of Professor E. J. EVATT, which deals with the prostate gland in the female. This paper is an important contribution towards the study of the development and homologies of the urethra and vagina in the two sexes, and it is reasonable to hope that the teaching of gynæcological text-books will soon fall into line with modern work instead of repeating the findings of the early days of embryological investigation, which are well known to every embryologist to be untrue.

The subject of intra-abdominal pressure has again engaged the attention of Dr. R. H. PARAMORE, who chose that subject for the Hunterian lectures.

Anatomy of the Chest and other Regions.

A very detailed account of the structure of the mammary gland has been given by Dr. E. RETTERER and Dr. A. LELIEVRE. The study has for its object the precise recognition of normal and abnormal phases in the changing histological appearances of the gland tissue. In a similar way the structure of the thymus gland has been exhaustively studied by Dr. R. PIGACHE and Dr. H. BECLERE. Professor KEITH has continued the study of the abnormal heart, and Professor FRANKLIN P. MALL has given a minutely detailed account of the musculature of the ventricles, which, however, possesses academic rather than practical interest.

Dr. T. WINGATE TODD has added a great amount of new knowledge to the study of cervical ribs, and the subject of the pressure exerted by normal and abnormal nerve trunks

[1] THE LANCET, April 15th, 1911.

upon the ribs. This is a question to which an increasing importance has become attached, since it has the most direct bearing upon the interpretation of not uncommon and very distressing clinical conditions.

Embryology and Anthropology.

A large contribution has been made to pure embryology, but since at present it has not all fitted into the greater scheme of useful knowledge—the knowledge which must be placed at the disposal of the man who intends to treat the diseases of the human body—it is difficult to appraise it at its proper value here.

Anthropology has claimed the work of many anatomists; Professor KEITH has done much to follow the traces of early man, and the year has been especially marked as an epoch in the study of the mummy and the ancient Egyptian, for since the Survey of Nubia has completed its labours and Professor G. ELLIOT SMITH has examined the vast amount of human material, the mummy has lived in a clearer light than he has ever known since the day he was wrapped.

Obituary.

Anatomy has suffered a heavy loss, and progress made seems trivial, when death has claimed two such men as THOMAS DWIGHT, Parkman Professor of Anatomy at Harvard, and PAUL POIRIER, Professor of Anatomy at Paris.

THE NAVAL, MILITARY, AND INDIAN MEDICAL SERVICES.

ROYAL NAVAL MEDICAL SERVICE.

On introducing the Naval Estimates last March the First Lord of the Admiralty stated that effect had already been given to many of the recommendations of the Committee of Inquiry on the Medical Service, and that others connected with financial questions were in process of settlement. The new regulations were promulgated in September and fully dealt with in our issues of that month. As Admiral DURNFORD'S committee had reported in July, 1909, it would seem that great deliberation had been exercised in dealing with its recommendations. The reforms have been received, on the whole, with satisfaction, and we trust will result in the establishment of the Naval Medical Service as one of equal attraction and popularity with that of the army.

The chief points are: an improvement of pay all round, the establishment of a new naval medical school for the training of young officers and for post-graduate instruction, and the recognition of the status of the medical officer of the senior flagship of a fleet. This officer will now be principal medical officer of the fleet, and will be on the staff of the Commander-in-Chief. A step has thus been taken in breaking down the complete independence (and isolation) of individual ships and their medical officers which has distinguished the past. More important than this is the increase of pay; it is only slight, but is accompanied by a grant of charge pay in many more instances than heretofore, and the increased rates are given after short intervals of service. Allowances, however, have not been increased, and are not equal to those of executive officers of corresponding rank. A change of title from the unwieldy Inspector or Deputy Inspector-General of Hospitals and Fleets has been made to Surgeon-General and Deputy Surgeon-General. There are probably good reasons why the distinctive appellation of Admiral was not found to be suitable for use in conjunction with a professional designation.

The most important advance, however, is the establishment of a Naval Medical College at Greenwich. This step is frankly on the lines of the evolution of the medical service of the army. Haslar will still be retained for certain purposes, such as instruction in hospital administration and physical training, just as Aldershot, *mutatis mutandis*, supplies part of the course for army medical officers; while the laboratory courses will be carried out at Greenwich, where also there exist ample facilities for the study of clinical tropical medicine and of hygiene. The *genius loci* of the Royal Hospital, and the fact that laboratories and college accommodation already exist there, also the proximity of the Seamen's Hospital, will, we feel sure, unite to make this new institution a keen rival of the Army Medical College at Millbank.

The executive control of the sick berth staff has, however, not been committed to the naval medical officer; nor has the vexed question of allotment of cabins according to the relative rank of the surgeon been dealt with. To the general public these matters may appear trifles, but such is not the case; we think they will have to be settled before the service can become as attractive as it should be to the best type of medical candidate. It was admitted by Mr. MACNAMARA in the House of Commons in November that the deficiency of medical officers was 60.

A commencement has been made in the formation of a medical reserve for the navy, and the result so far is said to be satisfactory. Also, arrangements have been made with civil hospitals for the supply of additional trained nurses in the event of war; this new force is to be known as Queen Alexandra's Royal Naval Nursing Service Reserve, a sesquipedalian designation which, as an example of unwieldiness, takes the place of the now disused title of Deputy Inspector-General of Hospitals and Fleets.

As Coronation honours, the K.C.B. was bestowed on Inspector-General D. M. SHAW and Inspector-General T. D. GIMLETTE; and the C.B. on Inspector-General C. GODDING, Inspector-General A. W. MAY, and Inspector-General H. J. TODD, and on Fleet-Surgeon P. W. BASSETT-SMITH; also the C.V.O. was conferred on Fleet-Surgeon A. R. BANKART.

THE ARMY MEDICAL SERVICE.

Scientific Research Work.

The publication of the work of the Sleeping Sickness Commission under Sir DAVID BRUCE has been continued during the past year, the latest results tending to increase the complexity of the problem of effective prevention of this disease. It has been established by experiment that cattle may act as a reservoir for the virus, and that healthy animals may be infected from them by means of Glossina palpalis, also that in the fly area they naturally harbour Trypanosoma gambiense. It is possible therefore that cattle and antelope within this area may act as a reservoir and so keep up the infectivity of G. palpalis for an indefinite period, though up to the present there is no proof that this actually occurs. Trypanosome diseases of cattle were investigated, and T. pecorum found to be the organism responsible, the carrier, however, not being definitely ascertained. From the ox in Uganda a trypanosome was recovered, which on investigation proved to be identical with T. brucei, the organism originally discovered by BRUCE in Zululand in 1894, and proved by him to be the cause of nagana, the tsetse fly disease. In the latest (eleventh) report it has been shown that the tsetse flies can remain infective for 96 days. Amongst the results of the work of this Commission may be noted the discovery of the existence of Mediterranean fever, under the name of *muhinyo*, in Uganda, where the principal focus of the disease is found along the eastern shore of Lake Albert Edward. M. melitensis was isolated. The disease was limited in its distribution, and there was no evidence to show how it originated.

The final report of the Sudan Sleeping Sickness Commission, by Captain R. G. ANDERSON, contains particulars as to the distribution of the two species of glossina

in the Southern Sudan, but it appears that there is no evidence of the existence of human trypanosomiasis in these regions, though cases occur in the Lado *enclave*, which may be a menace to the Bahr el Ghazal province. Active steps are being taken to limit the spread of the disease from the Congo State towards Lado and the Sudan. As previously mentioned, a further Commission to study Sleeping Sickness in Nyassaland has been appointed, and is already at work.

An important research has been carried out by Lieutenant Colonel W. H. HORROCKS on the viability and variation of B. typhosus. As to the former point, the conclusion come to is that the duration of life of this organism outside the body is, under natural conditions, very short. This harmonises very well with the result of practical experience, but is not to be taken as warranting any relaxation of sanitary precautions. The question of the variability or mutability of B. typhosus is one of extreme interest. The typhoid bacillus, under the influence of toxins formed in a mixture of the urine of a typhoid carrier with water (1 part in 9) appeared to become changed into a form closely resembling B. fæcalis alkaligenes; after intraperitoneal passage through a series of guinea-pigs the bacillus possessed many of the characters of B. coli. Moreover, a gradual mutation from a bacillus of typhoid type, derived from the urine of a typhoid carrier and subjected to intraperitoneal passage, was observed into a Gram-positive streptococcus. These researches are of great value and have led to considerable discussion.

Major H. W. GRATTAN and Captain J. L. WOOD have investigated the occurrence of paratyphoid fever in India, and consider that a considerable proportion of cases returned as "pyrexia of uncertain origin" are really due to infection by B. paratyphosus A; this has, of course, an important bearing on prophylaxis. A series of observations by Captain P J. MARETT on the life history of the phlebotomus fly in Malta, three species of which were studied, led to the formulation of preventive measures which are likely to be of considerable benefit, not only in Malta, but in other countries also, where it is now becoming recognised that "sandfly fever" is prevalent.

Experimental scientific work in quite another direction was carried out by a committee of the Advisory Board on the food requirements of men engaged on active service. Lieutenant-Colonel C. H. MELVILLE, Major W. W. O. BEVERIDGE, and other officers took part. Very careful observations were made and some valuable results arrived at, which will bear fruit in due season.

Military Medical Organisation.

The progress of Territorial medical organisation has not been as rapid, nor has it been marked with as much spirit, as was anticipated by the War Office authorities, and hoped for by ourselves. It was stated in the House of Commons in November that the shortage of medical officers was 283, and of other ranks 1759. In January Lord CHEYLESMORE presided over a meeting held for the purpose of starting a voluntary aid ambulance scheme in connexion with the Middlesex Territorial Force, and a general committee was formed. In the same month it was reported that 23 detachments of the Red Cross Society had been formed in Essex, and that a branch had been started at Bristol. A second ambulance section was added to the Dublin University contingent of the Officers' Training Corps in February. In the Scottish Lowland Division Sir GEORGE BEATSON stated in February that all the units but two had been provided for, and the field ambulances were at full strength; voluntary aid detachments had been formed, and the arrangements for general hospitals were complete. In spite of the excellent spirit thus displayed there seems to have been some delay in providing the necessary building accommodation in Glasgow. We understand, however, that the chief engineer of the command has taken up the matter. Three field ambulances are now organised in the (Liverpool) West Lancashire Division. An excellent precedent was afforded in August, when the Voluntary Aid detachments of the 2nd London Division, under Colonel A. CLARK, during their period of training in Kent coöperated with local detachments of the Red Cross Society and St. John Ambulance Association to carry out field medical arrangements on a considerable scale; this is the first occasion, as far as we know, that these local bodies and the Territorial Force have worked together in connexion with actual manœuvres.

The sanitary officers of the Territorial Force, whose services will be available on mobilisation, are as a body keenly alive to the importance of their duties and anxious to carry them out efficiently, but there is some want of clearness in the minds of many as to what these duties actually are. Lieutenant-Colonel MELVILLE, R.A M.C., addressed a largely attended meeting of the Society of Medical Officers of Health on this subject in February, the lecture being followed by a vigorous discussion. One speaker mentioned that in certain divisions the sanitary staff officers were consulted respecting the choice of sites for annual encampments and sources of water-supply, while in other places this was not the case. Mr. F. E. FREMANTLE thought that the Territorial Force would ultimately have to depend for sanitation on the civi sanitary administration. There can be little doubt that this would be the case, and there seems even now some need for closer intercommunication and coördination between the military authorities and the local health officers of districts to ensure that the knowledge possessed by the latter should be at the disposal of the former. If the local medical officer of health, or the county health officer, being also a member of the Territorial Force, were always to be on duty in his own area, there would be no difficulty; but obviously this could not always be the case. The Loamshire Territorials might have to serve in Downshire. The expert knowledge of the local health officer should certainly be at the disposal of the military medical authority at the earliest possible moment, and some speedy method of intercommunication appears to be a desideratum.

With developments in the fighting efficiency of armies, increased range of fire, and lengthened duration of engagements (some battles in the Manchurian war having lasted as long as ten days or more), alterations will have to be made in the arrangements for ambulance work. This subject was considered by Lieutenant-Colonel M. W. RUSSELL at a meeting of the United Services Medical Society early in the year, and the discussion that followed showed that much careful consideration will be required by the responsible staff at headquarters to ensure that the medical arrangements of our army are kept fully up to the mark in relation to those of the other great Powers. The manœuvres on Salisbury Plain during the summer and autumn of the past year were carried out on an extensive scale, and the medical and sanitary arrangements were more systematised than heretofore. It was evident that great progress had been made in the direction of efficiency, both in the Regular and in the Territorial units. The health of the troops was good, but owing to the scarcity of water some manœuvres had to be abandoned.

A modification has been made in the terms of appointment to the more important hospitals; the officers appointed will still be nominated by the Director-General, but the length of tenure will not be for a fixed period (generally three years) as heretofore. This rule is rendered necessary in order to ensure an equitable working of the roster for field officers. A most welcome departure from the official procedure of former

years is the publication in the corps journal of the list of officers required to proceed abroad during the ensuing trooping season, which gives fair warning to everyone when they are likely to have to leave home and where their destination is to be. At the same time it is notified that exchanges may be made by mutual consent, and, as regards India, that every effort will be made to meet the wishes of officers in regard to their being posted to any particular division. These evidences of courtesy and consideration on the part of headquarter authorities go a long way towards maintaining the spirit of contentment that is becoming general throughout the medical service of the army. In connexion with this we would commend to anyone interested in the service a capital speech delivered by the Director-General at the Army Medical College prize-giving on April 28th, and reported in the corps journal for June; this contains excellent advice and conveys a most attractive, yet not in the least exaggerated, idea of the actualities of the service.

Personnel.

On the occasion of the Coronation the Director-General received the honour of a K.C.B., and Companionships of the Bath were bestowed on Surgeon-General J. G. MACNEECE, Surgeon-General G. W. ROBINSON, and Colonel H. E. R. JAMES. Colonel P. B. GILES and Colonel G. S. ELLISTON of the Territorial Force received the same honour. In February Colonel E. J. E. RISK was appointed Commandant of the Royal Army Medical College, in succession to Colonel D. WARDROP, retired; the latter officer has since been appointed to the charge of the Officers' Convalescent Home at Osborne.

The retirement of Sir T. GALLWEY, K.C.M.G., C.B., after a career of great distinction, requires notice. This officer served in the Afghan war of 1879, the Egyptian expedition of 1882, the Nile expedition of 1884–85, the operations in Dongola in 1896, and in the later Nile operations of 1897 and 1898, being then Principal Medical Officer of the Egyptian Army. He was a divisional P.M.O. in the South African war, where his energy and resource, when P.M.O. of the force under Sir REDVERS BULLER, were strikingly manifested on several occasions.

The obituary list includes Surgeon-General J. A. MARSTON, C.B., a valued contributor to our columns for many years; Colonel T. LIGERTWOOD, C.B., formerly medical officer to the Royal Hospital, Chelsea; Surgeon-General R. W. MEADOWS, a Crimean veteran; and Colonel G. S. NICKERSON, at the early age of 40, formerly an officer of the corps, but who had latterly been in the service of the Egyptian Government, and at the time of his death was Governor of the Province of Sennaar.

THE INDIAN MEDICAL SERVICE.

With regard to the medical service in India we regret that we are unable to chronicle either a condition of contentment such as prevails in the Army Medical Corps, or of hope, such as animates the Naval Service in the possession of its new Warrant. Whether the prevailing sentiment can be described as one of resignation or of discontent is, perhaps, doubtful; we fear the latter state of mind is nearest the truth. Certain alterations have, however, been made in the Indian Medical Service regulations during the past year which indicate a desire on the part of the ruling authorities to meet the wishes of their officers. Revised rules have been issued as to the fees that may be claimed by medical officers when called in to act professionally outside their ordinary sphere of duty; the ill-advised rules that had been promulgated in 1907 and which were universally condemned have been rescinded, and an equitable and reasonable code issued in substitution. Unfortunately, some harm had already been done in diminishing the attractiveness of the Service, as shown by the reduction in number of the candidates for commissions.

A concession has been made in regard to acceleration of promotion; if an officer has not been able to obtain study leave in order to go through special courses, or to take special diplomas, and so has been prevented from qualifying for promotion while in the rank of captain, this acceleration is now open to him for four years after his promotion in the ordinary course. It has been pointed out, however, that there are difficulties, as it is, in the way of getting leave now that so much more leave is applied for by the younger officers than used formerly to be the case; it may result in a larger number being allowed to be absent at one time; or possibly study leave men might be placed on a different roster, so as not to interfere with the leave due to officers in the ordinary way. For officers who have entered since April of the present year permission will no longer be granted to remain in the service beyond 55 years of age, in the rank of lieutenant-colonel, in order to qualify for the 30 years' pension.

The appointments of honorary physician and honorary surgeon to the KING will in future only be held by officers on the active list; this alteration follows the recent change of the same kind in the Royal Army Medical Corps; and, as in that case, if the officer is a lieutenant-colonel, the appointment carries a brevet colonelcy only. Since the lamented death of Lieutenant-Colonel LESLIE last March the duties of Sanitary Commissioner with the Government of India have been carried on by the Director-General, I.M.S.; with a view to economy in administration several official appointments have recently been abolished, but up to the present no definite decision has been come to regarding that of the Sanitary Commissioner. The Secretary of State, in replying to Lord CURZON in the House of Lords in November, stated that, contrary to the proposal of the Government of India but in agreement with the views of the Indian Council, he considered that it was desirable to retain the appointment. We feel that Lord CREWE has come to the right decision in this matter; there is no doubt, and no one denies, that economy must be practised and that appointments which are not necessary must be abolished; but over and over again it has been shown that expenditure on prevention of disease really results in economy, and unless this department of administration and research is directly represented at headquarters of Government there is danger that due consideration will not be given to its requirements. It is possible that some improvement may be made in the mutual administrative relations of the work of the Director-General and of the Sanitary Commissioner.

A word of congratulation must be given to medical officers of both British and Indian Services who have given so much time and labour to ambulance work in India in connexion with the St. John Association; many ruling princes have supported the movement, and it has now taken root in the country and publishes an official gazette.

Scientific Work.

The research work of officers of the Indian Service during 1911 has included investigations on the Destruction of Fleas by Exposure to Sun (in connexion with plague prevention) by Captain J. CUNNINGHAM; on the Solubility and Absorbability of Quinine and its Salts, by Captain A. A. MACGILCHRIST; on the Cultivation of the Leprosy Bacillus, by Captain T. S. B. WILLIAMS; and on the Cultivation of the same and Treatment by means of a Vaccine prepared therefrom, by Major E. R. ROST. Sir D. SEMPLE, Director of the Kasauli Institute, has issued memoirs on the "Relation of Tetanus to the Hypodermic or Intramuscular Injection of Quinine," and on the "Preparation of a Safe and Efficient Antirabic Vaccine." This last-mentioned research is likely to prove of far-reaching importance for the inhabitants of India and other countries where rabies is prevalent. Captain WILLIAMS concludes that the organism of leprosy is

to be considered, not as an acid-fast bacillus only, but as a pleomorphic streptothrix, and consequently that the study of the mode of spread of the disease must be approached in a broader spirit than hitherto. (Colonel HORROCKS'S researches on B. typhosus, already referred to, lead to a similar conclusion in regard to typhoid.)

Captain R. MCCARRISON has made experimental studies on goitre at Gilgit; he believes the disease to be caused by presence in the blood stream of certain toxic substances of metabolic, bacterial, or putrefactive origin; the toxic agent is conveyed to the body in drinking-water, to which it gains access from the soil; it can be removed by filtration; the suspended matter of a goitrigenous water, separated by a Berkefeld filter, causes the disease. Further, it is a living organism, because it can be destroyed by boiling. The dose of infection is an important factor. Lastly, prevention consists in the provision of a pure water-supply.

The researches here noted constitute a fine record for one year by the small number of officers that have facilities for work of this nature. A contribution to practical sanitation has been made by Major W. W. CLEMESHA in his work on "Sewage Disposal in the Tropics," as to which he has had considerable experience. Major LEONARD ROGERS has written a standard work on "Cholera and Its Treatment," which will take the place of MACNAMARA'S treatise, admirable as that was in its own day.

Personal.

The honours bestowed in connexion with the Crowning of HIS MAJESTY the KING as EMPEROR of INDIA will be found recorded under "Honours to Medical Men," as well as other honours conferred. We have to record the retirement of Surgeon-General P. H. BENSON, the head of the Madras Medical Service; also of Surgeon-General H. HAMILTON, C.B., and of Colonel J. SHEARER, C.B., D.S.O., an officer who has held important appointments at headquarters, and has served in six campaigns.

The obituary list is a long one. Two officers of very high ability have been lost in the prime of life. Lieutenant-Colonel J. T. W. LESLIE, C.I.E., after having acted as professor of chemistry at Calcutta and secretary to the Director-General at headquarters, was at the time of his death Sanitary Commissioner with the Government of India. Major GEORGE LAMB was Director of the Pasteur Institute at Kasauli, and had done good research work on Mediterranean fever, snake venom, plague, and rabies. Colonel J. A. CUNNINGHAM, who died in Calcutta from cholera, had just been appointed Inspector-General of Hospitals in the Central Provinces. Colonel I. B. LYON, professor of chemistry and jurisprudence at Bombay, was well known as the author of "Medical Jurisprudence in India."

Of retired officers who have joined the majority Colonel W. P. WARBURTON, C.S.I., had filled the office of superintendent of the Edinburgh Royal Infirmary since his retirement from the service in 1899 until the present year. Surgeon-General W. B. BEATSON qualified as far back as 1846 and retired from the Indian army in 1883. Surgeon-General W. P. PARTRIDGE was a Mutiny veteran, and before that had seen active service in Persia. Sir HENRI BLANC, K.C.V.O., served in the Crimea and in the Chinese war of 1857–60. He was a member of the mission to King THEODORE of Abyssinia in 1867, and underwent great sufferings during his captivity. On release, and at the conclusion of the Abyssinian campaign, he returned to India, and became professor of surgery in Bombay. After retirement he settled at Cannes, where he soon found a large practice. His striking character, professional skill, and romantic career made him a most interesting personality.

The Civil Medical Profession in India.

No further decisive action has been taken by Government towards the establishment of an independent medical profession—that is, of a body of medical men apart from the Indian Medical Service, belonging to and educated in the country. At the Indian National Congress held in December, 1910, Sir BALCHANDRA KRISHNA moved a resolution requesting the Government of India to take early action as to the employment of independent practitioners in the higher posts of the civil branch of the Indian Medical Service. In the House of Commons, in February, Mr. E. KELLY put a question to the Secretary of State on the matter, and received a non-committal reply. In November, however, to Dr. C. ADDISON'S inquiry whether it was intended to appoint Indian medical men as professors in the medical colleges, Mr. MONTAGU replied in the affirmative, and said that the Secretary of State's decision to allow no further increase in the civil side of the Indian Medical Service was intended to have among its results the appointment of Indian medical men to professorships of the first rank. It does not appear, however, that during the year any concrete proposal has been made, or official action taken, in the direction of radical reform. We understand indeed that the difficulties have been found to be so great that any such extensive measure is regarded as impracticable. Nevertheless, the subject has been ventilated in various ways. A movement has been commenced to bring about the union of existing "unrecognised" medical schools in Calcutta and to improve their status. In connexion with a similar movement in Bombay, the system of limiting the teaching appointments to members of the Indian Medical Service was deprecated; but the Bombay Government considered that it was in this service that the best men for these appointments were to be found. At Lucknow two lectureships at the new Medical College (which was to be opened in October)—viz., those of forensic medicine and materia medica—are to be given to military assistant surgeons; these gentlemen, though often of wide experience and extensive practical knowledge, do not possess technically registrable qualifications.

Surgeon-General LUKIS, speaking at the Imperial Council, has specified three disabilities of the independent Indian practitioners under present conditions: (1) as private students they are debarred from the appointments of house physician and house surgeon at the large Government hospitals; (2) they have no facilities for post-graduate study; (3) they cannot obtain professorships at the medical colleges under Government. He acknowledged that these colleges cannot provide for nearly all the candidates for admission. He held that, in addition to the existing official institutions, there is ample room for unofficial colleges, staffed by unofficial professors; and considered this to be a case for the cordial coöperation of the public with the Government; by which, we presume, is meant the endowment of these institutions from private (that is, unofficial) sources. Two points occur to us in regard to this proposal: (1) Is there a sufficiency of properly qualified "non-official" professors, who *ex necessitate rei* would not be Europeans, to staff these colleges? (2) Will the large numbers of native practitioners who become qualified in this manner succeed in obtaining a living wage? Or will they not rather swell the ranks of that unemployed educated class, the existence of which is responsible for so much of the discontent in the country?

PHARMACY.

Scientific Work.

Although the attention of pharmacists has been mainly absorbed by legislative proposals and matters affecting their organisation, scientific pharmacy has not been neglected and some useful work has been accomplished. The progress of

pharmacy depends chiefly upon a comparatively small body of men, the results of whose work are usually communicated at the annual meetings of the British Pharmaceutical Conference or at evening meetings of the Pharmaceutical Society held during the autumn and winter months in London and Edinburgh.

The papers which were communicated at this year's Conference meeting at Portsmouth were, on the whole, of a useful character and of practical interest to the rank and file of pharmacists. A communication which attracted especial attention was that in which Mr. F. W. F. ARNAUD, the public analyst for Portsmouth, showed the urgent need for some control over the sale of so-called diabetic foods. He demonstrated the worthlessness of many of the foods which are claimed to meet the special requirements of diabetic subjects, showing that of 12 different samples examined the products of one manufacturer alone could be called satisfactory. The facts disclosed seemed to be of such importance that the executive of the Conference recently decided to draw the attention of the medical profession to what is undoubtedly a very unsatisfactory state of affairs. In another communication Mr. R. R. BENNETT showed that the widespread belief among clinicians that the commercial thyroid preparations vary considerably in their degree of physiological activity was due to the absence of an officially recognised standardisation process, and he suggested that an iodine standard should be fixed. Other papers of considerable value were read, but it will suffice to refer to these two in order to show that pharmacists in their endeavour to contribute to the advancement of pharmaceutical science are lending real assistance in the progress of therapeutics.

The communications read before meetings of the Pharmaceutical Society have, for the most part, been of an advanced type, indicating that in spite of the attention absorbed by matters of a trading character some pharmacists still find time to devote attention to the higher branches of their calling.

Much of the research work has been conducted with the object of assisting in the revision of the British Pharmacopœia, and the final report of the Committee of Reference in Pharmacy of the Pharmacopœia Committee of the General Medical Council was issued in the late summer. This report has formed the subject of further discussions, and the editors, Dr. NESTOR TIRARD and Professor H. G. GREENISH, will have before them a mass of valuable suggestions on which to base the monographs of the forthcoming edition. The report was of a lengthy and detailed character, and while subsequent criticism has shown that it would be inexpedient to adopt some of the recommendations, much praise is due to the committeee for the thorough and capable manner in which they have accomplished a difficult task.

British Pharmaceutical Codex.

The British Pharmaceutical Codex, which was published in November, affords further evidence of the steady work of those pharmacists whose labours are in the scientific field. Four years have gone by since the British Pharmaceutical Codex, 1907, was issued, and during that period the committee appointed by the council of the Pharmaceutical Society has been engaged in the task of revision. The new work bears witness to the assiduity and judgment of the committee, all of whom are pharmacists with the exception of Professor W. E. DIXON, who occupied the position of consulting pharmacologist. The plan of the book has been modified in several respects, and where drugs, chemicals, and galenical preparations described in the Codex are official in the British Pharmacopœia or the Pharmacopœia of the United States of America that fact is indicated.

Before concluding this brief summary of the progress of pharmaceutical science it should be mentioned that from the ranks of the younger pharmacists several new workers of promise have come forward during the year, and that in the higher branches of pharmacy there are no signs of decadence.

Proposals in Regard to Pharmaceutical Education.

Pharmaceutical education, on which the future progress of pharmacy so greatly depends, is in the melting-pot. The proposal to institute a compulsory curriculum for candidates and to divide the qualifying examination into two parts is still under consideration. The draft scheme submitted by the council of the Pharmaceutical Society to local associations and schools of pharmacy for criticism has been fully discussed, and a committee has been appointed to take into consideration the draft scheme in conjunction with the observations made upon it by the associations and educational bodies consulted and to formulate by-laws embodying points of agreement. The general feeling is undoubtedly favourable to a division of the qualifying examination, but there is a diversity of opinion as to the nature of the curriculum that should be imposed on candidates. It is thought in many quarters that if candidates for the first part of the examination were required to attend courses of lectures at recognised schools much inconvenience would be caused to apprentices in country places and small towns where educational facilities are lacking, and some modification of this part of the draft scheme will doubtless be necessary. A possible way out of the difficulty would be to accept certificates in certain subjects granted by technical colleges, and it might be found desirable to require candidates for the second part of the examination only to attend classes at recognised schools. Under the present system there is no compulsory curriculum of study of any kind, so that if the proposals are adopted only in a very modified form the new system would be an improvement on the old.

Imperial Pharmaceutical Reciprocity.

Until the Poisons and Pharmacy Act, 1908, came into operation the Pharmaceutical Society had no power to make the proposed alterations in the educational system; the same Act also gave the society power to make by-laws providing for the admission of colonial pharmacists to the British Register without examination. By-laws for the latter purpose have been drafted by the Council and will shortly be ready to receive the approval of the Privy Council. In most parts of the British Empire the British pharmaceutical diploma is accepted for registration in lieu of examination, but the Canadian boards of pharmacy have, during the last few years, declined to recognise the British diploma on the ground that their diplomas are not recognised in this country. When the new by-laws come into force the Canadian grievance will be removed and the door will be open for imperial pharmaceutical reciprocity. The new by-laws, however, will not permit of a similar interchange of courtesies between Great Britain and Ireland, for the English Pharmaceutical Society has no power to accept the Irish certificate and similarly the Irish Society is not empowered to accept the British diploma.

Pharmacists and the National Insurance Scheme.

The Government scheme of national sickness insurance naturally formed the chief subject of discussion among pharmacists during the second half of the year. The operation of the scheme will effect considerable changes in pharmaceutical practice, and it remains to be seen whether these changes will be beneficial or otherwise.

The Bill, as it was introduced in Parliament, was singularly deficient in regard to the provisions for pharmaceutical service. It merely provided that Friendly Societies and Local Health Committees should make provision "for the supply of proper and sufficient drugs and medicines," and that except in certain circumstances they

should not make arrangements for such supply with a medical practitioner at an inclusive fee. There was nothing in the Bill to prevent Friendly Societies from making arrangements which would have rendered them independent of pharmacists already established in business, and it was soon made clear that Friendly Societies intended to take advantage of the deficiencies of the Bill and to open central drug depôts and branch dispensaries from which insurance patients could be supplied with medicine. Had this intention been carried into effect pharmacy would have suffered a heavy loss and a large number of pharmacists would probably have been ruined. Such dispensaries would not necessarily have been under the supervision of a qualified medical or pharmaceutical practitioner, nor would they have been subject to the control of the Sale of Food and Drugs Acts, the Weights and Measures Act, or the Pharmacy Acts, so that the scheme, so far as it related to the supply of drugs, would have been open to many abuses.

On the initiative of the Pharmaceutical Society a campaign was begun with the object of obtaining such amendments as would secure that the dispensing under the scheme should be done by qualified persons; meetings of local pharmaceutical associations were summoned in all parts of the country, and a mass meeting—the largest gathering of pharmacists that has ever assembled—was held in London to protest against the inadequacy of the provisions made for the pharmaceutical service under the proposed scheme. A deputation arranged by the council of the Pharmaceutical Society and representing all branches of pharmacy waited on the Chancellor of the Exchequer and explained to him the alterations desired by pharmacists. Briefly, the more important of these were that Local Health Committees and not Friendly Societies should control the medical and pharmaceutical services, that insured persons should have free choice of chemist, that the drugs should be supplied and the dispensing done under qualified supervision, that payment should be made according to a scale of charges to be agreed upon between the Local Health Committee and those carrying on business as chemists within the area of the committee, and that pharmacy should be represented on the Advisory Committee and on the local committees.

During the Committee stage some of these principles were incorporated in amendments introduced by the Chancellor himself and others in amendments brought forward by Mr. W. S. GLYN-JONES, the Pharmaceutical Society's Parliamentary secretary, whose valuable services on behalf of pharmacists cannot be too highly praised. Several of the demands, notably that concerning representation on the administrative bodies, have not been conceded, and while pharmacists have not succeeded in obtaining all the privileges to which they claim to be entitled, their position under the Act is not altogether unsatisfactory.

The pharmaceutical sections of the "medical benefits" clause ensure that no arrangement for the dispensing of medicines shall be made—save in special circumstances—except with persons, firms, or bodies corporate entitled to carry on the business of a chemist and druggist under the provisions of the Pharmacy Act, 1868, as amended by the Poisons and Pharmacy Act, 1908. Such persons will be required to undertake that all medicines supplied by them to insured persons shall be dispensed either by or under the direct supervision of a registered pharmacist or by a person who for three years has acted as a dispenser to a medical practitioner or public institution. Drugs, other than poisons, and medical appliances may be supplied by unqualified traders, but medical practitioners will have the satisfaction of knowing that all medicines prescribed for insurance patients will be dispensed under qualified supervision.

Pharmacists, to a considerable number, are dissatisfied because more has not been conceded to them, but a little reflection should convince these that there is no just reason for serious complaint. There can be little doubt that the action of the General Medical Council in desiring the Government to place the dispensing of medicines in qualified hands greatly strengthened the case of the pharmacists. The threatening influence of the National Insurance Bill in the form in which it was introduced had the effect of showing pharmacists the need and the value of organisation. As a result the forces of pharmacy are better organised at the end of the year than they were at the beginning. Moribund associations have become active, new ones have come into existence, and in most localities the membership of associations has increased. The Council of the Pharmaceutical Society, with the object of keeping pharmacists throughout the country informed as to its policy and of assisting local effort generally, has appointed an officer whose special duty it is to control the movement, and, through the Council, direct it into proper channels. If the National Insurance Act does nothing else for pharmacy it has certainly given an impetus to pharmaceutical organisation.

Other Legislation and Regulations.

Concerning other legislation affecting pharmacy there is little to be said. The Shops Act, while it will not greatly interfere with facilities for obtaining drugs and appliances, compels pharmacists, like all other people who keep open shop, to give their assistants certain periods of leisure which the vast majority of them already gave without compulsion. The promised inquiry into the sale of secret remedies will be welcomed by pharmacists as a whole, and it is their hope that the inquiry will be followed by reasonably restrictive legislation. The new regulations as to the sale of the mineral acids and ammonia, while placing no limitations on the classes of traders who may sell these substances, should tend to prevent accidents. On the other hand, new regulations under Section 2 of the Poisons and Pharmacy Act have been sanctioned which will increase the facilities for obtaining poisonous compounds for use in agriculture and horticulture from unqualified shopkeepers and the danger attendant upon the careless distribution of poisons is consequently enhanced.

CHEMISTRY.

The Constitution of Matter and Transmutation.

There has again, of course, been a busy band of workers in the field of chemical science, but the progress has been of a steady rather than of a startling kind. During recent years chemists have almost overwhelmed themselves with amazing discoveries, and there appears to be an agreement amongst them now to stop and ponder over the significance of the secrets which they have wrested from Nature, in order, so to speak, that a place may be found for them in a harmonious system. Stock-taking has its advantages in scientific as well as in commercial affairs. The question, Where are we? is often worth asking in case a wrong turning has been taken. Rapid insights have been made of recent years into the constitution of matter; we have reduced the atom into hundreds of little bits which are regarded as nothing more than superposed layers of positive and negative electricity, and yet not so long ago the atom was held to be indivisible. The old alchemists' views have been revived by the electrical theory of matter, and we are beginning to think seriously again that all things are variants of one and the same material. Hence a stimulus has been given to obtain evidence of transmutation accomplished. The evidence, however, does not increase rapidly. The disintegration theory applies well enough to the unstable radium which resolves itself into emanation or niton and helium, and it seems to be established that these further

"degrade" into other distinct and rare elements. The familiar metals seem much too obstinate to yield to any energies which we are yet capable of applying to them to force them to resolve into inferior colleagues. It is true that Sir WILLIAM RAMSAY has reported that the energy of radium applied to copper salts has converted part of the copper into lithium, and similar experiments have indicated that thorium, zirconium, titanium, and silicon are degraded into carbon, but the experiments and results were on a microscopic scale. Conceivably, when it becomes possible to apply enormous strains to such familiar metals as gold, copper, lead, iron, and zinc, some tangible amounts of metallic products of degradation may be obtained and an actual demonstrable transmutation effected.

Industrial Electrolysis.

The electric current threatens to supersede classic chemical processes in the production of chemical substances and in the refinement of metals. The separation of sodium and the subsequent production of pure alkali from common salt is an example of the former, and the electrical purification of copper of the latter. Practically 90 per cent. of the copper used in the world is refined electrolytically. About 80 per cent. of the original copper contains arsenic, minute quantities of which vitiate its conducting properties. The offending metal is removed by electrolysis, and pure copper is thus obtained for electrical purposes—a case of electricity ministering to its own needs. The increasing production of aluminium in a pure state is again due to an electrolytic process.

The Origin of Diamonds.

The question of the origin of the diamond has been further discussed, and it seems to be concluded now that inorganic carbon as opposed to organic carbon is the starting point. One view is that carbon monoxide and carbon dioxide are caught in molten iron and there compressed by the closing together of the cavities. The enormous pressure forces a union of the oxygen with the iron and leaves crystal carbon. The fact that diamonds are associated with iron in their native surroundings supports this view. Graphite and coal are accounted for as products of organic matter, but it is contended that the origin of the diamond must be placed in pre-organic times.

A New Method of Chemical Analysis.

Sir J. J. THOMSON has employed the positive rays to determine the nature of the gases present in a vacuum tube. The method, he says, enables us to determine, not merely whether an element—say, for example, oxygen—is present in the tube, but will tell us in what form it occurs, whether, for example, it is present in the atomic as well as the molecular condition, and whether there are allotropic modifications present, such as ozone, O_3, and other still more complex aggregations. The method is capable of dealing with much smaller quantities of matter than the methods formerly employed by chemists, and is "capable of detecting transient phases in the processes of chemical combination." It is confidently hoped that this ingenious and pretty device will be of service in throwing light on one of the most interesting and mysterious problems in either physics or chemistry—the nature of chemical combination.

Industrial Syntheses.

Industrial synthetic products are increasing with amazing rapidity, and bid fair to render us, in regard to certain products, independent of natural supplies. Caoutchouc, camphor, indigo, veronal, caffeine, and many varieties of perfume, afford examples, and it is quite possible that even organic foodstuffs—e.g., protein—will eventually be successfully and economically built up from their elements.

In calling attention to these triumphs of the synthetic chemist, Professor EMIL FISCHER referred to the resemblances between chlorophyll and the colouring matter of the blood. He pointed out that chlorophyll and the colouring matter of the blood are closely allied chemically. "This indicates," he added, "a kind of blood relationship between the plant and animal kingdoms. It must, however, be of great antiquity—i.e., it must go back to the time when there was no distinction between the two kingdoms."

The Absorption of Oxygen by the Lungs.

Dr. J. S. HALDANE and Dr. C. GORDON DOUGLAS have continued their interesting work upon this subject. Their recent results indicate that the lung epithelium is excited directly or indirectly to active secretion of oxygen inwards by products of metabolism proceeding from the muscles and other tissues when their oxygen supply is insufficient to meet ordinary requirements. That such insufficiency actually occurs during muscular work, and when air with a low partial pressure of oxygen is breathed, has already been shown. It is pointed out that the results are of special interest in connexion with the phenomena of adaptation to very high altitudes, and throw a new light on the physiology of mountain climbing and balloon ascents, and of ordinary muscular work.

CONTRIBUTIONS FROM "THE LANCET" LABORATORY.

The work of chemical investigation in THE LANCET Laboratory has been heavy during the year. The inquiry, begun in 1910, in regard to the chemistry of the cup of tea has been finished, and the final report was published recently in THE LANCET of Dec. 2nd, 1911. The first report appeared in the first number of the year. The total analyses published in connexion with this investigation amounted to 590. New analytical methods were devised, and it seems to have been established that in good teas caffeine and tannin occur in a definite relationship as a compound—viz., caffeine tannate. In indifferent teas one or the other substance occurred in excess. It was shown that so long as tannin was combined chemically with caffeine to form a tannate its astringent qualities were in abeyance. An infusion of tea rarely coagulates milk, which would be the case if free tannin were present. Analysis showed that this compound contained 1 of caffeine to 3 of tannin. The compound can be prepared artificially from commercial tannin and caffeine, when it shows the same composition as that found in tea infusion. When caffeine and tannin occur together in the proportions of 1 to 3 in tea infusion the expert taster, it was found, invariably regarded a tea yielding such an infusion as of superior quality. The objections to tannin in the free state cannot be raised against tannin in the form of caffeine tannate, and the action of the alkaloid may be modified by association with tannin. Caffeine tannate is very soluble in hot water, but is to a large extent precipitated in the cold. It is very soluble in quite weak alcohol and in weak alkali. The fact that an infusion of tea is alkaline keeps the caffeine tannate in solution. This may to a great extent be precipitated by adding acid to neutralise the alkali.

We hoped to publish during the year the results of an inquiry into the character and amount of the soot deposit in London, but the inquiry entailed so much analytical work that only recently have the results been extracted from the calculations. We hope to publish these in an early number.

We are glad to be able to record the success of the Rag Flock Bill. From time to time we have placed evidence in front of our readers from our Laboratory in proof of the urgency of this industry being placed under simple sanitary control.

In THE LANCET of Jan. 28th an account from the Laboratory was published of a diabetes cure which had given rise

to symptoms in a patient suggesting the presence of an alkaloid. No alkaloid, however, was found, and ultimately it was concluded that the dried leaves submitted were polygonum hydropiper, commonly known as water pepper.

During the year a considerable discussion arose in the lay press as to the impoverishment of the food value of bread effected by modern milling methods. We have for long urged that it was desirable to maintain a high efficiency of nutritive value in wheat flour, and that something should be done to check the production of flours owing their whiteness to chemical bleaches or the use of "improvers." According to recent investigations it is probable that the nutritive value of bread is determined by biological factors connected with the germ.

We welcomed a valuable report from the Local Government Board upon skimmed condensed milk in relation to its ignorant use in infant feeding. For a good many years we have drawn attention to this subject, and in this report we were glad to find that steps were recommended to control the sale of skimmed condensed milk for infant feeding. Its practical freedom from fat, of course, renders it absolutely unfit for such a purpose.

During the year we took up once again the question of flannelette. It was represented to us that, in spite of the recommendations of the Coroners' Committee in 1910 that the Merchandise Marks Act, 1887, should be amended by adding a provision making it penal to describe as uninflammable material which will not stand prescribed tests, there was not only no abatement in the sale of inflammable material, but inflammable material was being sold claiming to be non-inflammable. We made a number of tests with materials bought in the open market, and found that though there was evidence that steps were being taken to supply the public with a safer material, there were still cheap flannelettes obtainable which were dangerous. In some cases it was found that the materials had been rendered perfectly safe by treatment with certain metallic salts. The report contained 48 drawings showing the way various materials had behaved when submitted to ignition tests.

During the year several new inventions were tested in the laboratory, and the results reported in our columns.

A special article upon Strathpeffer Spa appeared in THE LANCET of July 1st as the result of a visit of our Laboratory Commissioner to a health resort at which many developments in the direction of modern hydro-therapeutics have been recently effected.

During the year we have analysed and reported upon numerous quack medicines submitted to us by our readers.

Under the heading of "Analytical Records and Reports from THE LANCET Laboratory," 67 preparations comprising drugs, special foods, waters, and beverages were dealt with. The total number of analyses made in connexion with this column and with the special reports reviewed above was 804.

GENERAL MEDICAL COUNCIL.

The usual two meetings of the General Council of Medical Education and Registration were held during the year, and the proceedings showed the Council to be ready to deal in a business-like way with matters closely concerning the well-being of the medical profession.

At the summer meeting the Council resumed consideration of the position of the Preliminary Sciences in the medical curriculum, and as a result the Education Committee were instructed to report to the Council on the alterations necessary in the regulations for the registration of medical students so as to make those regulations consistent with the position under which it is optional for a student to take the preliminary scientific subjects of his curriculum elsewhere than at a medical school. Sir HENRY MORRIS pointed out the difficulty which the Council must have in justifying regulations which gave to students, their parents, or their masters, a misleading impression that it was absolutely necessary that the courses in the Preliminary Sciences should be taken in the medical curriculum, an error that had led to the withdrawal of boys from public schools sooner than was necessary. Similar questions arose under a motion by Sir HENRY MORRIS to place on a list of institutions approved by the Council for the commencement of medical study secondary schools which had been duly inspected and recognised by a licensing body. The motion, amended so as to include the approval also of the Students Registration Committee for such schools, was passed by the Council, and as a consequence at the winter session a list of schools which had been recognised by the English Conjoint Board were approved by the Council. Sir HENRY MORRIS has intimated that at the next session he will bring forward a suggestion, in the form of a motion, that the Council should recommend to all the licensing bodies, universities, and schools, that the study taken at these approved institutions should not be allowed—even if it extended over two or three years—to count as more than six months of the medical curriculum.

At the summer meeting the Council appointed a committee of 9 members, 3 nominated by each Branch Council, to consider the Insurance Bill and make representation through the Privy Council to the Government on any matters within the province of the Council. The Council saw that the proposal affected the medical profession in many ways of which they might be compelled to take cognisance; especially might medical education be endangered by a decline in the efficiency of the clinical schools attached to the hospitals. The committee made a certain number of proposals of amendment through the Lord President to the Government, which were advocated at a personal interview with the Chancellor of the Exchequer and other officers of the Treasury. The correspondence with the Chancellor which ensued was made public, and the Chancellor's personal agreement with the recommendations of the Council was recognised in amendments. The Council, however, found that, as time went on, the changes in the Bill, which when they were made appeared satisfactory, were in later stages modified by further amendments; and at the winter meeting, held on Nov. 28th and following days, the President's address implied that the administration of the medical benefits might be placed in an unsatisfactory position and that the stability of clinical hospitals was in distinct danger.

Certain penal cases during the year attracted the widespread attention of the public as well as of the medical profession. Three medical men working in connexion with the Sandow Health Institute appeared before the Council at the summer meeting on a charge of unprofessional conduct made by the British Medical Association, with the result that one of them was removed from the Register of the profession, while the consideration of the cases against the other two was postponed until the next session. Thereupon one gentleman dissociated himself from the institute, while the other elected to remain in connexion with it, considering that the administration of the institute had been altered to meet the objections of the Council. Concerning the last case interesting proceedings took place, the practitioner being represented by able counsel, who attempted to convince the General Medical Council that his client's behaviour had been, during the six months' probation, of a professional character. The Council, taking the opposite view, decided to postpone a decision as to the practitioner's name remaining on the rolls of the profession for a further period.

During the year there was an election of Direct Representatives of the medical profession for England and Wales,

which resulted in the re-election of Dr. H. W. LANGLEY BROWNE and Dr. H. A. LATIMER and the election of Mr. T. J. VERRALL; Dr. J. A. MACDONALD having earlier in the year been elected to fill the vacancy caused by the regretted death of Dr. L. S. MCMANUS. In Scotland Dr. NORMAN WALKER was re-elected without opposition, as also was Dr. LEONARD KIDD in Ireland.

BRITISH MEDICAL ASSOCIATION.

The annual meeting of the Association was held at Birmingham from July 25th to 29th, and was in every way a great success. Large numbers of members and ladies travelled to the Midland capital, and the beautiful weather added much to their pleasure. The scientific and social arrangements were well planned and carried out. The Representative meeting, which occupied the four days before the opening of the annual meeting, was largely occupied with important matters relating to the National Insurance Bill. The Representative body discussed the Bill in committee, and its proceedings were *in camerâ*; only the resolutions finally arrived at by the committee being placed before the Representatives, who confirmed them all. The substance of their conclusions was to reaffirm all the main points of the Association's policy, as already declared and embodied in the familiar six-fold demand, and the Council was instructed to take every means in its power to carry this policy into effect.

At the annual general meeting on July 25th the retiring President, Sir HENRY BUTLIN, vacated the chair for Professor ROBERT SAUNDBY, the President-elect, who delivered his address on the Present Position of the Medical Profession the same evening. This was published in THE LANCET of July 29th, together with the Address in Medicine by Dr. BYROM BRAMWELL, and the Address in Surgery by Mr. JORDAN LLOYD. The scientific work of the meeting was spread over four days, and was divided into 16 sections, some of which held joint sessions. The business of the sections was conducted in the class-rooms of the University building in Edmund-street. This is very central and conveniently close to the Midland Institute and the town hall, which were set apart for addresses and large meetings and the reception of visitors. A compact and instructive pathological museum, illustrating various special subjects, was arranged in some of the laboratories adjoining the meeting-places of the scientific sections. The annual exhibition of instruments, foods, and drugs was held in Bingley Hall and attracted a good deal of interest; it was formally opened by the Lord Mayor on July 25th.

The sections this year were five less than at the seventy-eighth annual meeting in London in 1910, and less also than in 1909. Last year there were separate sections for anatomy and physiology, bacteriology was divorced from pathology and otology from laryngology, and there were independent sections for anæsthetics and for the Services. The 21 sections of the London meeting established a record in the division of labour at the Association's annual gatherings, and this multiplicity of interests was justified by the special circumstances of a great meeting in the metropolis; but the reduction in number at Birmingham this summer was probably well advised, and little seemed to be lost by the bringing together of closely allied subjects. Nevertheless, we hope the Section of Anæsthetics will be revived. Many papers of high clinical and scientific value were read at the sectional meetings, and there were some interesting debates. These were reported in the issues of THE LANCET of August 5th, 12th, and 19th.

But, except for the brief days in July allotted to the business of the scientific sections, the energies of the British Medical Association have been almost completely absorbed throughout the year by the grave problems arising out of the National Insurance Bill. Thus the scientific side of the Association's work has been greatly overshadowed by the medico-political side, and the executive officers have been continuously engaged upon the double task of shaping the policy of the Association and of attempting to carry that policy into effect. The leaders of the Association have been brought into direct contact with the political machinery of the country, and the action taken by the Council and the decisions reached by the Representative Body have been fraught with momentous consequences to members of the Association, to the medical profession, and most of all perhaps to the public.

HONOURS TO MEDICAL MEN.

New Year Honours.

The list of honours which was issued at the beginning of the new year included the names of the Right Hon. LEANDER STARR JAMESON, who was made a baronet, and those of Dr. HORATIO BRYAN DONKIN, Mr. FREDERIC S. EVE, Dr. DAVID FERRIER, Dr. GEORGE NEWMAN, Dr. JOSEPH MICHAEL REDMOND, and Lieutenant-Colonel DAVID SEMPLE, R.A.M.C., who received knighthoods. Sir STARR JAMESON, although the work of his maturer life has not been medical, owes his success in no small measure to his early medical training. Sir HORATIO BRYAN DONKIN, medical adviser to the Prison Commission and late Director of Convict Prisons, did much useful work as a member of the Royal Commission on the Care and Control of the Feeble-minded, while he also assisted the Departmental Committee on the Inebriates Acts and the Treatment of Inebriety. Sir FREDERIC S. EVE is senior surgeon to the London Hospital and a consulting surgeon to the Evelina Hospital. His work as a clinician and a pathologist is well known. Sir DAVID FERRIER has to his credit original researches in neurology which have been recognised and appreciated in all parts of the civilised world. Sir GEORGE NEWMAN, chief medical officer to the Board of Education, is a member of the Board of Hygiene Studies at the University of London, and is the author of some important publications on public health and bacteriology. As we have before pointed out, the best testimonial to the work which he has done is his suggestive report on the inspection of school children to the Board of Education for the year 1909, which was presented to Parliament at the end of November, 1910. Sir JOSEPH MICHAEL REDMOND is an ex-President of the Royal College of Physicians of Ireland who has written much and ably on medicine. Lieutenant-Colonel Sir DAVID SEMPLE, of the Royal Army Medical Corps, is Director of the Central Research Institute at Kasauli, who has done much good work on bacterial vaccines and serum-therapy generally. In addition to these honours the Kaisar-i-Hind gold medal was conferred upon Lieutenant-Colonel HENRY SMITH, of the Indian Medical Service, civil surgeon of Amritsar; on Major THOMAS WALTER IRVINE, of the Indian Medical Service, late residency surgeon at Mewar; and on Major R. J. BLACKHAM, R.A.M.C., sanitary officer of the First Division, Indian Army.

Coronation Honours.

Among the names in the list of honours issued in connexion with the KING'S Coronation were those of Mr. HENRY T. BUTLIN, Dr. WILLIAM OSLER, Dr. JAMES F. GOODHART, Sir CHARLES B. BALL, and Sir W. THORNLEY STOKER. Each of these gentlemen received a baronetcy. Sir HENRY T. BUTLIN, the distinguished ex-President of the Royal College of Surgeons of England, is also the Past-President of the British Medical Association. His public services to medicine have been great and varied. Sir WILLIAM OSLER, Regius professor of medicine in the University of Oxford, who is famous throughout two continents, has enriched the literature of medicine with many works of high scientific and literary

value. Sir JAMES F. GOODHART is an eminent clinician whose name is a household word in general medicine as well as pædiatrics. Sir CHARLES B. BALL, the President of the Royal Academy of Medicine in Ireland, is a distinguished member of a distinguished family. He is the representative on the General Medical Council of the University of Dublin. Sir W. THORNLEY STOKER, consulting surgeon to the Richmond, Whitworth, and Hardwicke Hospitals, Dublin, is another eminent member of the Irish medical profession. He is H.M. Inspector of Anatomy and Government Inspector under the Vivisection Act in that country.

Knighthoods were bestowed upon Mr. ANTHONY A. BOWLBY, Mr. RICHARD BRAYN, Dr. ALEXANDER DEMPSEY, Dr. FREDERICK W. HEWITT, the Hon. JOHN MCCALL, and on Mr. FREDERICK C. WALLIS. Sir ANTHONY A. BOWLBY, C.M.G., Surgeon-in-Ordinary to the King, served as senior surgeon in charge of the "Portland Hospital" in the South African war; Sir RICHARD BRAYN is Home Office Adviser in Lunacy and late medical superintendent of Broadmoor Asylum; Sir ALEXANDER DEMPSEY is a well-known Belfast obstetric physician; Sir FREDERIC W. HEWITT is anæsthetist to the King and physician-anæsthetist to St. George's Hospital; the Hon. Sir JOHN MCCALL is Agent-General for Tasmania in London and Member of the House of Assembly and of the Executive Council; and Sir FREDERICK C. WALLIS is surgeon to Charing Cross Hospital.

The honour of K.C.B. was conferred upon Inspector-General DOYLE M. SHAW, Inspector-General THOMAS D. GIMLETTE, Surgeon-General WILLIAM L. GUBBINS, C.B., Surgeon-General ADAM S. REID, C.B., Major RONALD ROSS, and Dr. BENJAMIN ARTHUR WHITELEGGE, C.B. Inspector-General Sir DOYLE M. SHAW saw active service during the Crimea and the bombardment of Alexandria, and was in charge of several naval hospitals before his retirement; Inspector-General Sir THOMAS D. GIMLETTE is the head of the Royal Naval Hospital, Haslar; Surgeon-General Sir WILLIAM L. GUBBINS is Director-General of the Army Medical Service; Surgeon-General Sir ADAM S. REID, Indian Medical Service, was lately principal medical officer of the Punjab Command; Sir RONALD ROSS is professor of tropical medicine in the University of Liverpool and the Liverpool School of Tropical Medicine; he was awarded the Nobel Prize for Medicine in 1902, and his services in the campaign against malaria are world famous; and Sir B. A. WHITELEGGE is H.M. Chief Inspector of Factories and Workshops.

The distinction of K.C.M.G. was conferred upon Dr. JOHN ROSE BRADFORD and Dr. JOHN PRINGLE. Sir JOHN ROSE BRADFORD is one of the two secretaries to the Royal Society, and among our foremost scientific physicians; Sir JOHN PRINGLE, C.M.G., is a member of the Privy and Legislative Councils of Jamaica.

Dr. BERTRAND DAWSON received the K.C.V.O. Sir BERTRAND DAWSON is physician-extraordinary to the KING and physician to the London Hospital.

The C.M.G. was conferred upon Dr. JAMES W. BARRETT, member of the council and lecturer of the University of Melbourne; Mr. DUGALD CHRISTIE, head of the Mukden Medical Mission; and Dr. T. ZAMMIT, Government analyst, Malta. The following were appointed C.B.'s: Inspector-General C. C. GODDING, Inspector-General A. W. MAY, Inspector-General H. J. MCC. TODD, and Fleet-Surgeon P. W. BASSETT-SMITH, of the Royal Navy; Surgeon-General G. W. ROBINSON, Surgeon-General JAMES G. MACNEECE, Colonel C. F. WILLIS, and Colonel T. GRAINGER, of the Indian Medical Service; Lieutenant-Colonel H. E. R. JAMES, R.A.M.C. (retired); Colonel G. S. ELLISTON, Administrative Medical Officer of the East Anglian Division; and Colonel P. B GILES. Colonel J. R. THOMAS was appointed Honorary Physician, and Colonel DAMER HARRISSON Honorary Surgeon to His Majesty for His Majesty's Territorial Force.

The C.V.O. was conferred upon Fleet-Surgeon A. R. BANKART, Mr. MILSOM REES, and Mr. MAYO ROBSON, and the M.V.O. upon Mr. WILLIAM FAIRBANK.

Dr. MICHAEL COX was made an Irish Privy Councillor. The Hon. Sir FREDERICK BORDEN, Canadian Minister for Militia and Defence, was made an Honorary Surgeon-General; and Sir JAMES REID, Bart., G.C.V.O., K.C.B., was granted by HIS MAJESTY an augmentation of arms in consideration of services rendered to His late Majesty KING EDWARD.

In connexion with the visit of the KING and QUEEN to Scotland after their Majesties' Coronation the honour of knighthood was conferred upon Dr. THOMAS SMITH CLOUSTON and Dr. JAMES ORMISTON AFFLECK. Sir THOMAS CLOUSTON retired from his position of superintendent of the Royal Asylum for the Insane, Edinburgh, in 1908. During his tenure of office there he brought about great improvements in the treatment, nursing, and housing of the insane, perhaps the most outstanding achievement being the completion of Craig House about 21 years ago. Sir JAMES AFFLECK is well known in Edinburgh as a practitioner and consultant. He has been thrice appointed examiner in medicine and clinical medicine at the University of Edinburgh, and for many years acted as examiner in medicine for the Royal College of Physicians.

The Durbar Honours.

In connexion with the crowning of HIS MAJESTY the KING as EMPEROR of INDIA, Surgeon-General CHARLES PARDEY LUKIS, C.S.I., and Surgeon-General FRANCIS WOLLASTON TREVOR, C.B. K.H.S., received Knight Commanderships of the Order of the Star of India. Surgeon-General Sir CHARLES PARDEY LUKIS is the Director-General of the Indian Medical Service and an additional Member of the Council of the Governor-General of India for making Laws and Regulations, and Surgeon-General Sir FRANCIS WOLLASTON TREVOR is Principal Medical Officer in India. Lieutenant-Colonel WILLIAM BURNEY BANNERMAN, I.M.S., Colonel GEORGE FRANCIS ANGELO HARRIS, V.H.S., and Lieutenant-Colonel ARTHUR RUSSELL ALDRIDGE, R.A.M.C., were made Companions of the Order.

In the list of Knights Commanders of the Order of the Indian Empire was the name of Surgeon-General ARTHUR MUDGE BRANFOOT, C.I.E., I.M.S. (retired). Surgeon-General Sir ARTHUR MUDGE BRANFOOT is President of the Medical Board of the India Office. Lieutenant-Colonel CHARLES MACTAGGART, I.M.S., Major LEONARD ROGERS, I.M.S., Major HENRY BURDEN, I.M.S., Lieutenant-Colonel JAMES REED ROBERTS, I.M.S., and Major FREDERICK FENN ELWES, I.M.S., received Companionships of the Order.

Colonel CHARLES JAMES BAMBER, I.M.S., received the C.V.O., and Lieutenant-Colonel CHARLES HENRY BEDFORD, I.M.S., was made a Knight Bachelor. Lieutenant-Colonel Sir CHARLES HENRY BEDFORD, I.M.S., is chemical examiner, Bengal.

The following officers received the "Kaisar-i-Hind Medal for Public Service in India" of the First Class:—Major ALBERT ELIJAH WALTER, I.M.S., Major ARTHUR GWYTHER, I.M.S., Surgeon Lieutenant-Colonel THOMAS JOSEPH O'DONNELL, K.G.F. Vols., V.D., Captain JASPER ROBERT JOLY TYRRELL, I.M.S., and Major WILLIAM HANCOCK TUCKER, I.M.S. Similar honours were conferred upon Dr. HERBERT F. LECHMERE TAYLOR, the Rev. JOHN CAMERON YOUNG, M.B., C.M. Glasg., and upon Dr. RAGHAVENDRA ROW.

Foreign Honours.

The Insignia of the Third Class of the Imperial Order of

the Medjidieh were conferred by the KHEDIVE of EGYPT upon Dr. ERNEST COTTON FISCHER, professor of ophthalmology at the School of Medicine, Cairo; Dr. REGINALD GOWER KIRTON, Chief Medical Inspector of Prisons, Cairo; and Dr. P. C. E. TRIBE, honorary physician to the Anglo-American Hospital at Cairo. Captain GEOFFREY WALLACE GRAINGER HUGHES, R.A.M.C., received the Order of the Fourth Class. Major FREDERICK FITZGERALD CARROLL, R.A.M.C., and Captain ROBERT BARCLAY BLACK, R.A.M.C., were the recipients of the Imperial Ottoman Order of the Osmanieh, Fourth Class.

His Majesty the KING of ITALY conferred upon Surgeon-General JAMES GAUSSEN MACNEECE, principal medical officer, 8th (Lucknow) Division, India, a Commandership of the Order of St. Maurice and St. Lazarus.

The decoration of the First Class, Third Division, Imperial Chinese Order of the Double Dragon was conferred by His Majesty the EMPEROR of CHINA upon Mr. WILLIAM HAROLD GRAHAM ASPLAND, M.D. Toronto, medical professor at the Union Medical College, Peking; Dr. JOHN MAITLAND STENHOUSE, of the Union Medical College, Peking; and Dr. BERNARD SCORE BROWNE, of the Church Missionary Society Hospital, Ningpo, in recognition of valuable services rendered during the recent epidemic of pneumonic plague.

Dr. HENRY CURWEN received the decoration of the Fourth Class of the Order of El Aliyeh from the SULTAN of ZANZIBAR.

HOSPITAL FUNDS.

Metropolitan Hospital Sunday Fund.

Under the presidency of Sir THOMAS VEZEY STRONG, the just retired Lord Mayor of London, the year's collection resulted in a total of £67,015 14*s.* 8*d.*, the collections in the various places of worship amounting to £37,061, or £3717 less than in 1910. The Metropolitan Cathedral of St. Paul headed the list with £4323. The following are the largest collections from contributing places of worship: Christ Church, Lancaster Gate, Rev. Prebendary GURDON, £1009; St. Michael, Chester-square, Rev. J. GOUGH MCCORMICK, £672; St. Peter, Eaton-square, Rev. Prebendary STORRS, £470; St. Mary Abbots, Kensington, Rev. Prebendary PENNEFATHER, £422; Holy Trinity, Chelsea, Rev. H. R. GAMBLE, £400; St. Mark, North Audley-street, Rev. H. P. CRONSHAW, £293; St. Paul, Onslow-square, Rev. Prebendary WEBB-PEPLOE, £289; St. Paul, Knightsbridge, Rev. F. L. BOYD, £280; St. Peter, Cranley-gardens, Rev. W. S. SWAYNE, £231; St. Jude, South Kensington, Rev. Prebendary EARDLEY WILMOT, £225; St. George, Hanover-square, Rev. F. N. THICKNESSE, £216; Wimbledon Churches, Rev. J. ALLEN BELL, £213; Westminster Abbey, Very Rev. the DEAN, £203; St. John, Paddington, Rev. E. P. ANDERSON, £200; St. Columba, Pont-street, Rev. A. FLEMING, £311; Theistic Church, Swallow-street, Rev. CHARLES VOYSEY, £200; West London Synagogue, Rev. M. JOSEPH, £319; Great Synagogue, the CHIEF RABBI, £237; Essex Church, Kensington, Rev. F. K. FREESTON, £233; Westminster Chapel, Rev. G. CAMPBELL MORGAN, £296; City Temple, Rev. R. J. CAMPBELL, £152; St. Paul's Presbyterian Church, Westbourne-grove, Rev. J. W. WALKER, £100; St. Andrew's Presbyterian Church, Frognal, Rev. R. MACLEOD, £130; Greek Church, Bayswater, the ARCHIMANDRITE, £75; Brompton Oratory, Rev. H. D. S. BOWDEN, £54; Carmelite Church, Kensington, Very Rev. the PRIOR, £50; Victoria Park Christian Evidence Association, Mr. T. COLE, £74; Dutch Church, Austin Friars, Rev. S. B. DE LA FAILLE, £40; German Church, Camberwell, Rev. O. GOEHLING, £46; Metropolitan Tabernacle, Rev. A. G. BROWN, £40; Wanstead Society of Friends, Mr. THEO. GODLEE, £30; Jackson's Lane, Highgate, Wesleyan Church, Rev. W. A. LABRUM, £32; Gordon-square Catholic Apostolic Church, Mr. H. S. HUME, £24. The sum of £8000 was received from the executors of the late Mr. GEORGE HERRING, which, with £17,790 0*s.* 6*d.*, the amount of dividends upon investments of residue transferred to the Fund, made a total of £25,790 0*s.* 6*d.* on this account. Mr. WILLIAM HERRING gave a donation of £1000, and a further payment of £125 was received on account of Mr. C. E. LAYTON'S bequest. The amount awarded to 166 hospitals and institutions, 59 dispensaries, and 32 nursing homes was £56,710. During the year the Fund sustained a severe loss by the deaths of the CHIEF RABBI, the Rev. Dr. WALLER, Mr. RICHARD FOSTER, and Mr. JOHN HAMPTON HALE, the chairman of the Finance Committee.

King Edward's Hospital Fund.

The amount received by this Fund up to Dec. 8th for general purposes, and after payment of expenses, was £176,745. The amount available for distribution among London hospitals was £151,000, as against £150,000 in 1910. The number of hospitals applying for grants was 105. In addition, 43 convalescent homes and seven consumption sanatoriums applied for grants, and £6500 were distributed among these institutions, as against £5000 in 1910. The scheme for placing beds in country consumption sanatoriums at the disposal of patients in London hospitals has proved very advantageous. The satisfactory condition of the Fund is, of course, largely owing to the interest taken in it by the Royal family. HER MAJESTY the QUEEN has increased her annual subscription to 100 guineas, while last year the KING increased his subscription from £500 to £1000, and the PRINCE of WALES gives a subscription of £100. The KING has also allocated to the Fund a share amounting to £2000 in the munificent Coronation gift of His Highness the MAHARAJA OF GWALIOR. Among the receipts of the Fund for the year was an anonymous gift of £10,000. The Fund lost by death among its members Lord NORTHCOTE, the Rev. Dr. ADLER, and the Rev. J. GUINNESS ROGERS. Dr. A. R. RAINY, a most valuable visitor for the Fund, also passed away during the year. Mr. FRY, one of the honorary secretaries, has retired from that position, and Mr. JOHN G. GRIFFITHS has been invited to take his place.

At a meeting of the League of Mercy held at St. James's Palace on Dec. 14th it was stated that the League had collected £19,306 for the year, or £1881 less than in 1910. It was proposed to distribute £19,200.

Hospital Saturday Fund.

The annual income of the Hospital Saturday Fund, which was founded in 1873 for the purpose of obtaining help for the metropolitan hospitals and kindred institutions from those who were not reached through the operations of the Metropolitan Hospital Sunday Fund, now exceeds £34,000, which is obtained from some 8000 places of business. The annual report shows that help is obtained from practically every trade, friendly society, and club, the employees of the London County Council, the borough councils, the railway companies, the Metropolitan Water Board, the General Post Office, the Royal Arsenal, Woolwich; the Royal Small Arms Factory, Enfield Lock; the Royal Victoria Yard, Deptford; the Dock Companies, and so forth, and the members of the Metropolitan and City police. Since its foundation the Fund has collected and distributed among the medical charities of London £549,545. In recent years there have been about 200 participating institutions. The Fund, recognising the great importance of early treatment in cases of tuberculosis and other chest diseases, has endowed beds at the Benenden Sanatorium, Kent; at the Mount Vernon Hospital, Hampstead, and its sanatorium at Northwood; at

the Fairlight Home, Hastings; and at the Eversfield Hospital, St. Leonards. Forty-three beds are at present endowed, the patients paying, as a rule, 7*s.* 6*d.* per week for the first six weeks, after which time the rates are arranged in accordance with the means of the patients and other circumstances. The sum thus received enables the Fund to assist many applicants who could not otherwise be relieved. During the present year the various departments of the Fund have made steady progress, and it is hoped that when the books are made up in January they will show a record collection for 1911. Up to Dec. 16th the total receipts of the Fund amounted to £25,061, as against £23,536 in the corresponding period of 1910.

SANITATION ON THE RIVIERA.

The Drainage of Cannes.

After a lapse of some years we have renewed our investigations concerning the general and sanitary condition of the health resorts on the French Riviera. Of these the best known and most patronised by the highest classes from England is the old fishing village that Lord Brougham discovered, which has now become the flourishing town of Cannes. It seems curious that though this winter station owes its great prosperity almost exclusively to the patronage of English families, the British influence has failed to bring about the adoption of some satisfactory drainage scheme. At Cannes, built along the sea shore, there is insufficient fall for water carriage drainage. Endless disputation arose as to the mechanical methods that might be adopted to overcome this natural difficulty. At last a system has been adopted, and this year we were able to record that Cannes now possesses sewers to the length of 25 miles, draining 2000 out of a total of 2600 houses and villas. This is much better than nothing, though still removed from perfection. The main collector has practically no fall—barely 1 in 1000, and the current is only kept going by 55 automatic flush tanks, which discharge their contents six times a day. About half the sewage falls into the sea at the end of the Mole, but the rest flows out of six minor outfalls, which are too near to the shore, and, as the figures given above show, in spite of 30 years' agitation, more than 20 per cent. of the houses still retain the old-fashioned and dangerous cesspool system. This is the more inexcusable as the sewer tax levied where houses drain into public sewers amounts to a much smaller sum than the cost each householder must pay for the emptying of his cesspool. In the disposal of household refuse the municipality of Cannes has shown more initiative. Instead of creating a nuisance by sorting this refuse or incurring great expense by cremating it in a destructor, it is simply buried. Along the arid coast line, at some distance from the town in the La Bocca district, great and broad trenches are dug in virgin soil. The refuse carts tilt their contents into these trenches, the earth is shovelled over the rubbish, and five years are allowed for the process of natural purification. After that time it can all be dug up, the hard core—pots, pans, basins, tins, &c.—sifted away, and a fine inodorous earth remains, which is sold for market gardening and other such purposes.

Reckless Disposal of Refuse at Mentone.

This affords a very favourable contrast to the abominable desecration of the beautiful road to Sospel from Mentone. There the refuse from some 10,000 people is thrown into ravines and allowed to fester and ferment in the open air, breeding millions of flies, and spoiling the country for some distance around. In the meanwhile the town authorities are discussing what sort of destructor they ought to employ. Then they have discovered, but too late, that the heat generated in the destructor might help to provide motive power for the manufacture of electricity and thus reduce the cost of lighting the town.

Fertilising with the Refuse of Nice and Marseilles.

At Nice the neighbouring arid and stony banks of the rivers Paillon and Var supply enough ground to receive the town refuse for a hundred years or more. The town is creating assets for the future by converting arid into fertile soil with the aid of its town refuse. The greatest scheme, however, of this description is realised in the desert of La Crau. Here, under the able guidance of M. DE MONTRICHER, the rocky soil is blown up with dynamite, and trains bring every day the fresh refuse from Marseilles which is poured over the broken rock. To-day a part of the desert is green with the almond and olive trees that are growing there.

The Drainage of Monaco and Monte Carlo.

The Principality of Monaco, always enterprising and often ahead of its neighbours, was the first to set an example in regard to the disposal of refuse. In 1898 it spent £3400 in the building of a destructor, and even before the cholera epidemic of 1885 attempts had been made to dig down into the hard rock, so that the old historic town of Monaco might have a proper sewage system. In 1894 the English system of drainage by water carriage, and gravitation with the Shone elevators and ejectors where there was not a sufficient fall, was adopted for the entire Principality. There are now 15 miles of sewers, and no more sewage is allowed to flow into the port. Old sewers have been rebuilt and new ones laid, automatic flush tanks help to scour the sewers in dry weather, and the work has been well done throughout with but one very important exception. The scheme provided that the street sewer inlets should be also utilised as sewer ventilators. Pipes reaching to the top of the nearest house were to be connected with each inlet, yet this latter and essential part of the work has for some unaccountable reason been neglected. Since describing this defect His Serene Highness PRINCE ALBERT has informed us that "careful note would be taken of the just and useful observations" we had made. We consequently hope it will not be long before the sewers of the Principality are ventilated throughout.

Monaco's Model and New Hospital.

In one respect, and this is to a large extent due to the personal intervention and generosity of PRINCE ALBERT, the Principality has acquired undoubted pre-eminence. The new hospital is one of the best situated, most perfect, and luxurious buildings of the sort on the whole of the Riviera coast. The rocky mountain side, 81 metres above the sea, was hewn out to make a broad terrace, absolutely sheltered, facing the southern sun and the blue Mediterranean. Here well-built pavilions with solid stone walls, connected by sheltered colonnades and surrounded by beautiful flower beds and trees, have been constructed regardless of expense. In this manner the PRINCE has spent an enormous sum for the benefit of his people. The results are so excellent—and we published the very favourable statistics of the operations performed—that any number of persons who are not Monegasques have resorted to ingenious stratagems so as to gain admittance to this beautiful hospital. Nor is this institute intended only for the poor. At one end of the sheltered terrace there is the Villa Albert, fitted as a luxurious nursing home, where well-to-do patients of all nationalities are received. The charge varies from 8*s.* to 16*s.* a day according to the room occupied. This is a great boon to the traveller. The hospital is managed like a first-class hotel, the patient is attended by the physician he selects and pays, but there is a staff of fully trained nurses to carry out the medical advice given. Many other details and an illustration were given concerning this hospital, which was

inaugurated when the International Conference of the International Association of the Medical Press met at Monaco in 1902. Sufficient time has now elapsed to be able to show that the mortality from major surgical operations performed in this hospital is below the average.

THE HOUSING PROBLEM IN SOUTH WALES.

The very rapid increase of population due to the development of the mining industries has led to a house famine. Of recent years the population has multiplied fourfold, and private enterprise utterly fails to provide a corresponding addition to the housing accommodation. Indeed, there is every interest to keep the supply below the demand, for it is thus possible to charge extravagant rentals. The abuses resulting were studied on the spot and described at some length in THE LANCET early this year. Merthyr Tydfil, the valley of the martyrdom of the British Princess TYDFIL, has well sustained its early reputation. Here and to this day thousands have been brought prematurely to the grave by low wages and bad housing. These martyrs of modern industrialism are so numerous that the Valley of Martyrdom is no misnomer for this sinister part of Wales. Local Government Board inquiries, and pictorial descriptions written by Mr. GEORGE R. SIMS and other journalists agree with what our Sanitary Commissioner further described and denounced. Fortunately all these complaints and criticisms have produced some improvements, and the local authorities of Merthyr, Swansea, and elsewhere have now themselves built houses to be let at low rentals. But the difficulty is not all on one side. It is no easy matter to deal with the people themselves, for they generally prefer a central but unwholesome, overcrowded tenement to removing to the outskirts of a town where cheaper, ample, and healthy accommodation can be obtained. In South Wales there is a further difficulty caused by the fact that social wrecks drift there from all parts of the country. They work for something less than a living wage and take no interest whatever in their homes. Such tenants soon degrade good property and are the despair of all reformers, while their bare-footed and rag-clothed children are a disgrace to the community. This has led to the enactment of a very stringent and useful by-law at Merthyr, dated Oct. 21st, 1907. It applies to private lodgings in private houses where the rent is under 5*s.* unfurnished and 7*s.* 6*d.* furnished. As a great many workmen's families living in a cottage take in a lodger it brings the whole of this large class under sanitary control. The by-law gives the right of inspection both night and day, insists on 400 cubic feet of space for each adult, and not only states that the place must be kept clean, but gives full details as to how, and how often, the premises are to be cleaned. In this respect, and in regard to the "over and under" houses built against the side of precipitous hills, we gave details that were curious and instructive, arising from the peculiar local conditions. We are glad to think that some progress has been made and some improvements realised, while the chief cause of regret is the long delays that have occurred.

OBITUARY.

From the beginning of this year up to and including our issue of Dec. 23rd we have had the mournful duty of inserting in our columns special obituaries of well-known and highly appreciated medical men.

Mr. HENRY POWER died on Jan. 18th at the age of 81. He was consulting ophthalmic surgeon to St. Bartholomew's Hospital, and for more than 40 years a regular member of the staff of THE LANCET. He was an untiring as well as a methodical worker, and his industry and love of order enabled him not only to keep abreast of ophthalmological literature, but also to read widely in anatomy, physiology, and botany, and to record his candid views upon what he read with regularity. Mr. FREDERICK MELLAND died on Jan. 17th, having nearly completed his ninety-third year. He was connected for many years with the Chorlton Dispensary and the Ancoats Hospital, Manchester. Mr. GEORGE BIRT died on Jan. 25th, aged 64 years. He held the post of honorary surgeon to the Stourbridge Dispensary. Mr. CALEB BARRETT died in January at the age of 90 years. He had been medical officer to the Southern Dispensary in Bath, and also medical officer to the Abbey and Weston districts of the Bath union. Mr. JUSTIN THEODORE VULLIAMY, who died on Jan. 23rd at the age of 41 years, was assistant surgeon to the Rugby Hospital. Dr. FREDERICK WILLIAM PEARCE JAGO died on Feb. 1st at the age of 93 years. He practised at Plymouth for 50 years; he took a great interest in all matters connected with Cornwall and was the author of "The Ancient Language and the Dialect of Cornwall." Lieutenant-Colonel ALFRED WILLIAM FREDERICK STREET, D.S.O., died on Jan. 30th at the age of 58. He entered the Indian Medical Service in 1877 and saw much active service. From 1887 to 1902 he held the position of Deputy Sanitary Commissioner under the Government of Bombay, in which he did very valuable service, both in the sanitary control of a very wide area and in the suppression of plague itself. Dr. JAMES EDMUNDS, who died on Feb. 16th, was born in 1832. He was consulting physician to the London Temperance Hospital. He was one of the founders of the British Medical Temperance Association and its president from 1876 to 1879. Dr. CHARLES ALEXANDER MACMUNN died in February at the age of 58. He was consulting physician to the Royal Orphanage, Wolverhampton. He wrote particularly on the relation of chemistry to medicine. Dr. ARTHUR FRAME JACKSON died on Jan. 25th from plague at Mukden, where he was on the staff of the large hospital as medical missionary.

Dr. ANDREW SMART died on March 8th at the age of 86. He was consulting physician to the Royal Infirmary, Edinburgh. He is said to have been the first to discover the presence of micro-organisms in living tissue, the discovery being made in connexion with his work on rinderpest in 1865. Dr. WILLIAM PALEY died on March 13th at the advanced age of 94. He was at one time physician to the Peterborough Infirmary. Dr. LEONARD STRONG MCMANUS died on March 26th at the age of 54. He interested himself in municipal and political affairs with great advantage to those with whom he associated. He was highly esteemed by the profession, as was shown by his election to the General Medical Council as one of the Direct Representatives for England. Dr. THOMAS REID died on March 23rd at the age of 80. He was a member of the staff of the Eye Infirmary at Glasgow. He was also honorary consulting oculist to the Western Infirmary and Sick Children's Hospital in that city. He obtained a gold medal for his display of microphotographic work in the University of Turin. Surgeon-General JEFFERY ALLEN MARSTON died on March 31st at the age of 79. He was honorary surgeon to H.M. the KING. He had a distinguished military service, and on his retirement he became President of the Army Sanitary Committee as well as a member of the Indian Medical Board. For 30 years, whenever his conditions of employment allowed, he was a regular member of the staff of THE LANCET. Dr. HENRY PICKERING BOWDITCH, who died at the age of 71, was the *doyen*, and in reality the founder, of the American School of Physiologists. After prolonged study in Europe he returned to Boston (United States), and the present splendid position of the Harvard Medical School is due to him, as dean, more than to any other one man.

Dr. HENRY JAMES STOKES, of Highbury, who died on

April 12th at the age of 88, was one of the few remaining links which connected the medical profession of the present day with that of the earlier nineteenth century. He commenced medical practice in Islington in 1848, and continued to discharge its duties until his seventy-ninth year. Mr. FRANCIS JOHN MARSHALL died on April 1st, aged 68 years. He held the post of resident medical officer to St. George's Hospital for 30 years with remarkable success. Dr. WILLIAM WALKINSHAW MACREIGHT died during April at Torquay at the age of 83. He was for many years physician to Torbay Infirmary and to the Western Consumption Hospital. He was consulting physician to the Torbay Hospital up to the time of his death. Dr. HENRY SIMPSON died on April 13th at the age of 82. He was consulting physician to the Manchester Royal Infirmary, to the Manchester Hospital for Consumption and Diseases of the Throat, to the South Manchester Hospital for Diseases of Women and Children, and to the Manchester Ear Hospital. He was an authority on sanitary progress and reform. Dr. ARTHUR JAMES MACDONALD BENTLEY died on April 19th. He had held the posts of colonial surgeon to the Straits Settlements, medical adviser to the Johore Government, and physician to the SULTAN. Of late years he practised alternately at Llandrindod Wells during the summer and at Cairo during the winter. Dr. JOSEPH CARNE ROSS died at the age of 66. He was physician to Ancoats Hospital, Manchester. Mr. SAMUEL KNAGGS died on April 23rd at the age of 82. He was consulting surgeon to the Huddersfield Infirmary, and took an active part in the administration and development of the institution. Mr. JOHN TATHAM THOMPSON died on April 28th at the age of 52. He was consulting ophthalmic surgeon to the Cardiff Infirmary. He had made a special study of miner's nystagmus. Surgeon-General BEATSON (Indian Army) died on April 26th at the age of 86. He was the author of "The Indian Medical Service: Past and Present." Dr. CLAUDE CLARKE CLAREMONT died on April 30th at the age of 56. He was physician to the Royal Portsmouth Hospital. The Rev. ROBERT ELLIOTT, L.R.C.S. Irel., died on April 25th. He was secretary of the medical committee of the Church Missionary Society, being in charge of the medical missions of that society. Brigade Surgeon Lieutenant-Colonel ISIDORE BERNADOTTE LYON died on April 27th at the age of 71. He was for a time physician at the Jamsetjee Jeejeeboy Hospital; he was dean in medicine of the University of Bombay in 1888, and was created C.I.E. in the following year. He wrote a text-book on "Medical Jurisprudence," of which several editions have since appeared.

Mr. EDWARD MILLS GRACE died on May 20th at the age of 69. He was coroner for the lower division of Gloucestershire and a well-known cricketer. Dr. EDWARD H. DOUTY died on May 27th at the age of 48. He was at one time assistant surgeon and surgeon in charge of the gynæcological department, Addenbrooke's Hospital, Cambridge, and lecturer on midwifery in the University. Later he settled at Cannes and became surgeon to the Asile Evangelique, Cannes, and to the Queen Victoria Memorial Hospital, Nice. Dr. PETER HUME MACLAREN died on May 20th at the age of 74. He was consulting surgeon to the Royal Infirmary, Edinburgh. He was President of the Royal College of Surgeons, Edinburgh, in 1894 and 1895. He contributed largely to the knowledge of specific disease.

Dr. ALEXANDER BRUCE died on June 4th. He was physician to the Edinburgh Infirmary and one of the most noted neurologists in Europe. He devoted a large amount of time to the *Review of Neurology and Psychiatry*. His "Illustrations of the Mid and Hind Brain" and his "Topographical Atlas of the Spinal Cord" are acknowledged as among the finest things of their kind. Sir RUBERT WILLIAM BOYCE died on June 16th at the age of 48. He was Holt professor of pathology at the University of Liverpool and dean of the Liverpool School of Tropical Medicine. He published various papers on the pathology of the nervous system, which earned for him the Fellowship of the Royal Society. Later he became absorbed in tropical research, and served personally on expeditions of the Liverpool School of Tropical Medicine. Mr. ALFRED STILEMAN BOSTOCK, who died on July 1st at the age of 65, was a prominent practitioner at Chichester. Dr. THOMAS LAW WEBB died on July 3rd, aged 65. He practised at Ironbridge, Shropshire. He was profoundly interested in the etiology of cancer; his best-known work was that on "Cancer Houses," founded on observations made in his own registration sub-district of Madeley, and extended over a period of some 60 years. Dr. HERBERT TIMBRELL BULSTRODE died on July 21st at the age of 52. He was Medical Inspector to the Local Government Board, and lecturer on preventive medicine at Charing Cross Hospital Medical School. He delivered the Milroy lectures before the Royal College of Physicians of London in 1903 on the Causes, Prevalence, and Control of Pulmonary Tuberculosis. He was commissioned to make special inquiry into the sanatorium treatment of tuberculosis, the result being the volume entitled "Sanatoria for Consumption," a standard work which was published by the Local Government Board. Dr. JOHN BEDDOE died on July 19th at the age of 85. He was at one time physician to the Royal Infirmary and consulting physician to the Children's Hospital, Bristol, and to the Bristol Dispensary. Able physician as he was, it was as an anthropologist that he made his mark in this country and abroad. He also made valuable researches in archæology. Dr. JOHN DUNNELL RAWLINGS died on July 17th at the age of 43. He was surgeon to the Dorking Hospital.

Dr. SAMUEL JONES GEE died on August 3rd at the age of 71. He was consulting physician to St. Bartholomew's Hospital. His work on "Auscultation and Percussion" attained a sixth edition. In 1871 he delivered the Goulstonian lectures at the Royal College of Physicians of London, in 1892 the Bradshaw lectures on Signs of Acute Peritoneal Diseases, and in 1899 the Lumleian lectures on Bronchitis, Pulmonary Emphysema, and Asthma. Dr. GEORGE FIELDING BLANDFORD died on August 17th, aged 82. Throughout his professional life he was associated with psychological medicine. He was for many years lecturer on psychological medicine at St. George's Hospital Medical School. He wrote a text-book on "Insanity and its Treatment," which passed through four editions. At the time of his death he was President of the Society for the Relief of Widows and Orphans of Medical Men. Dr. FRANK PIERCE FOSTER died on August 13th at the age of 69. For 31 years he was editor of the *New York Medical Journal*. Dr. LEONARD CANE died on Sept. 2nd at the age of 63. He was consulting physician to the Peterborough Infirmary. Mr. ARTHUR BEADLES died on August 19th. He had a large practice at Forest Hill.

Mr. JAMES REID died on Sept. 12th at the age of 90. He was consulting surgeon to the Kent and Canterbury Hospital. Dr. FREDERICK WILLIAM PAVY died on Sept. 19th at the age of 82. He was consulting physician to Guy's Hospital. His literary work was both voluminous and important. It was mainly devoted to the physiology of digestion and the subject of diabetes. His views on diabetes, if not always in accord with contemporary opinion, were based upon his own experimental researches and clinical observation. In 1882–83 Dr. PAVY became Censor of the Royal College of Physicians, an office which he held again in 1891.

Dr. JOHN HUGHLINGS JACKSON died on Oct. 7th at the age of 76. He was consulting physician to the London Hospital and to the National Hospital for the Paralysed and

Epileptic. By his death English neurology has suffered a loss the extent of which it would be difficult to exaggerate. Many of his researches culminated in discoveries which made his name familiar wherever medicine is taught the world over. The psychologist of to-day has adopted his hypothesis of "levels" in the central nervous system; the physiologist has established the truth of his views on the functions of the motor cortex and of the cerebellum; the clinician and the pathologist are reaping in many fields where he sowed. Dr. JOSEPH BELL died on Oct. 4th. He was consulting surgeon to the Royal Infirmary, Edinburgh. He possessed an extraordinary faculty of detecting the ordinary routine of his patients' careers or the environments in which they lived; this faculty led Sir A. CONAN DOYLE to create his famous hero SHERLOCK HOLMES. Mr. LOUIS STROMEYER LITTLE, who died on Oct. 4th at the age of 70, was at one time surgeon to the London Hospital, and then went to Shanghai, where he was surgeon to the Shanghai General Hospital. Mr. GEORGE THOM died on Oct. 8th at the age of 65. He was consulting surgeon to the Royal Albert Hospital, Devonport. Sir H. J. BLANC died on Sept. 30th at the age of 80. He served in the Crimea and retired from the service with the honorary rank of deputy surgeon-general. To the late King EDWARD, when Prince of Wales, he proved of signal service, the reward for which came to him in the K.C.V.O. Dr. WILLIAM RICHARD HUGGARD died on Oct. 10th. He practised at Davos, where he was British Consul. Mr. CHARLES VERNON HITCHINS died on Oct. 11th at the age of 84. He was honorary surgeon to the Weston-super-Mare Hospital and Dispensary. Dr. ALFRED PETER HILLIER died on Oct. 24th at the age of 53. He spent many years in South Africa, and was a prominent member of the Reform Committee at the time of the Jameson raid. He was joint editor of *Tuberculosis*. Politics attracted him strongly, and he was Member of Parliament for North Herts. Dr. STANLEY SMITH died on Oct. 25th in the sixtieth year of his age. He was physician to the Railway Clearing System Superannuation Fund Corporation.

Sir SAMUEL WILKS died on Nov. 8th at the age of 87. He was consulting physician to Guy's Hospital. Of his literary works, the most important was the publication in book form, in 1859, of his lectures on Pathological Anatomy. He was President of the Royal College of Physicians of London from 1896-99. In 1897 he was created a baronet and was awarded the Moxon gold medal. He also received the appointment of physician to Their Royal Highnesses the Duke and Duchess of CONNAUGHT, and that of physician-extraordinary to Queen VICTORIA. Dr. JOHN ALFRED COUTTS died on Nov. 1st at the age of 60. He was physician to the East London Hospital for Children. He contributed several articles upon children's diseases to ALLCHIN'S "Manual of Medicine" and to the "Encyclopædia Medica." Dr. WILLIAM WILFRED WEBB died on Nov. 18th at the age of 54. He joined the Indian Medical Service in 1882, and attained the rank of major. He took great interest in biographical, genealogical, and heraldic work. Dr. WILLIAM HENRY WEBB died on Nov. 14th at the age of 58. He was medical officer of health of the Kingsbridge urban and rural districts, and honorary surgeon to the Kingsbridge Cottage Hospital. He was also Surgeon-Lieutenant-Colonel of the 2nd Battalion Devon Regiment (T.F.), V.D. Dr. FRANCIS THOMAS BOND died on Dec. 5th at the age of 77. He was medical officer of health, Gloucestershire combined district. Mr. HENRY ROBERT HEATHER BIGG died on Dec. 7th at the age of 58. He devoted himself to the study of orthopraxy. Dr. WALTER WYMAN died on Nov. 20th. He was Surgeon-General of the United States Public Health and Marine Hospital Service. Under his administration many far-reaching and important improvements regarding the health of the United States—civil, naval, and military—were effected.

Dr. EDMOND FAURIEL TREVELYAN died on Dec. 11th at the age of 52. He was senior honorary physician to the Leeds Public Dispensary and physician to the Leeds General Infirmary. He was one of the most ardent supporters of the Leeds Association for the Prevention and Cure of Tuberculosis. Dr. GEORGE HUBERT MAPLETON died on Dec. 10th, aged 53. After 14 years of medical practice in the West Indies he went to Goudhurst, Kent, in 1896, and practised there until his death.

THE NATIONAL INSURANCE ACT.

The passing of the National Insurance Bill into law within eight months of its first presentation to Parliament has been to the medical profession the most important public event of the year. It is unnecessary for us here to enter into a detailed discussion of the medical position under the Bill as it first stood or under the Act as it now stands, because week by week we have reviewed the situation as it changed or developed, and numerous correspondents have freely ventilated their opinions of the measure in our columns. A general survey shows that for a short time after the Chancellor of the Exchequer launched his scheme the attention of the medical profession, like that of many other interests affected, was more occupied with the admirable principles underlying the Bill than with the true significance and value of the methods proposed. But from the first it was shown by us that the Bill as it was drafted involved grave risks to the practice of medicine, and later disclosures and discoveries only emphasised the need for this warning. Time after time we insisted that, notwithstanding the general motive of the Bill, grave danger must lie in forcing through a scheme which proposed to improve the public health by a vast extension of club practice. It soon became obvious that the Bill as it stood could not be accepted by the profession, and the British Medical Association took in hand the task of formulating the minimum demands which must be conceded by the Government before the profession would coöperate in working the scheme. Hence arose the so-called six cardinal points, and upon these a large majority of the profession agreed to take a stand, pledging itself by inference to undertake the work if these were definitely granted and guaranteed. Throughout the summer and autumn and into the winter the leaders of the Association carried on negotiations with the Chancellor, and meanwhile the Bill passed through the House of Commons, undergoing innumerable changes in its course, but not coming into line with medical requirements in any definite or satisfactory manner. For a time indeed it seemed as though a deadlock had arisen, because certain concessions made by the Chancellor with the idea of appeasing medical men caused a serious outbreak of hostility towards the Bill in the large Friendly Society world. The gathering storm, however, cleared suddenly, and the medical profession then found that what had been grudgingly given to it with one hand had been largely taken away with the other.

Recent events are too fresh to need recapitulation. Mr. SMITH WHITAKER'S appointment, the passing of the Act, and the great protest meetings in London, Manchester, Birmingham, and Sheffield are all affairs of yesterday. The present position can scarcely be considered satisfactory. That there is division of opinion within the profession cannot be denied or ignored. But in spite of this we trust that a common basis of action may yet be found upon which all may loyally and honourably unite. The questions whether the Council of the Association have done the best that could have been

done, whether they gave good or bad advice to the Representative Body, or whether they should have sanctioned their Medical Secretary's appointment, must, alas, remain open for discussion. But the more that these questions can be thrust into the background, the better will be the chance for a development throughout the whole profession of a real spirit of union. A highly organised profession, seeking no legislation on the point in question, suddenly finds itself, by certain sections of a complicated measure, involved in a struggle for existence. While the struggle is still going on, the Bill, in a manner against which no protest can be too vigorous, becomes the law of the land. We have to decide upon a common line of policy, justifying every step of our resistance.

Annotations.

"Ne quid nimis."

METROPOLITAN HOSPITAL SUNDAY FUND.

AT a meeting of the constituents of the Metropolitan Hospital Sunday Fund, held at the Mansion House on Dec. 21st, under the presidency of the Lord Mayor, the report of the Council for the year 1911 was received. The Council were re-elected for the year 1912 with the addition of the Ven. Archdeacon of London, the Rev. Prebendary Perry, the Rev. J. Allen Bell, the Rev. H. A. Hall, the Rev. Simpson Johnson, Sir Thomas Vezey Strong, Mr. Arthur Finch Charrington, and Mr. Andrew Motion; and June 9th was fixed for Hospital Sunday, 1912. The figures of the report will be found in THE LANCET of Dec. 9th, p. 1641, and in our present issue, p. 1876. The Bishop of London moved that the report be received, and in doing so remarked that the Fund formed a golden bridge between rich and poor and was a wonderful bond of union and goodwill between people of all denominations. Sir J. Bell seconded the motion. Mr. H. S. Stowe asked why the Distribution Committee of the Fund had accepted the assurance of the authorities of St. George's Hospital that money paid to the medical school from the funds of the hospital really went to the sick poor, when the King's Fund had not been satisfied, and as a consequence had made no grant. Sir William Church said that no grant had been given by the King's Fund to St. George's Hospital because the authorities of that hospital had not applied for one, and read a letter from Mr. A. W. West, the treasurer of the hospital, which stated in the clearest manner that not one penny of the money subscribed by the Metropolitan Hospital Sunday Fund, or from any other source to the general funds of St. George's Hospital, was used for any other purpose save for the treatment of the sick poor. Mr. Stowe then moved an amendment which would have had the effect of deleting from the report the amount already given to St. George's Hospital. The Lord Mayor declined to accept this amendment because the money had already been paid. Subsequently the Rev. L. S. Lewis proposed an amendment in the following terms: "That as King Edward's Hospital Fund, after careful investigation into the accounts of St. George's Hospital, has felt itself unable to make a grant to that hospital, the Metropolitan Hospital Sunday Fund refuses to encourage what King Edward's Fund condemns, and wishes it to be an instruction to the Distribution Committee next year to fall in line with the King Edward's Fund on this matter." This was seconded by Mr. Stowe, and after a long discussion, which was taken part in by, among others, Sir Sydney Holland, Sir William Church, the Bishop of London, Mr. A. W. West, and the Rev. G. M. Hanks, the amendment was withdrawn, after the Bishop of London had remarked that the word of Mr. West was sufficient for him, though he appreciated the opinions behind the amendment. The Lord Mayor has promised that he will inquire into the matter during his year of office, and he will be doing a great public service if he can arrive at the proper solution of a grave difficulty.

THE SANATORIUM MOVEMENT IN DENMARK.

IN a recent lecture Dr. H. Rördam has given an interesting account of the vigorous campaign against tuberculosis which has been carried on in Denmark during the last decade. At the close of the year 1900 there were only three consumptive hospitals or sanatoriums in Denmark. Ten years later there were 12 sanatoriums, with a total of 1069 beds for the working classes, and 52 Government hospitals for tuberculosis, with a total of 1113 beds. Thus in the course of ten years 2147 beds were provided for cases of tuberculosis among the working classes, the Government paying three-quarters of the cost of treatment. Denmark, therefore, with a population of 2½ millions, has practically got for every 1000 inhabitants one bed devoted solely to tuberculous patients. The credit for this energetic campaign against tuberculosis is largely due to the Danish National Society for the Prevention of Tuberculosis. This society, which has now existed for ten years, has promoted about 500 lectures on tuberculosis throughout the country; it provided in 1908 a central station in Copenhagen, to which 300 doctors have sent 1750 patients. 12,200 suspect cases have been medically examined and 12,300 visits have been paid by the nursing staff attached to the station. With the money provided by the sale of the society's "Höstblomst," or autumn flower, over 300 children have been given suitable treatment. Owing largely to the society's activity a number of laws have come into force dealing with the notification of phthisis and with general hygiene. It is accordingly somewhat disappointing to find that whereas the mortality from phthisis fell rapidly in the period 1880 to 1900, its decline has been much slower in the last decade, and it even shows a tendency to rise in 1905. Probably this rise was more apparent than real, as it synchronised with the introduction of compulsory notification of phthisis; and it is certain that a greater proportion of cases of phthisis are now diagnosed as such than was formerly the case. It must also be borne in mind that in such a disease as tuberculosis it is easier to reduce a high to a low death-rate than to reduce a low death-rate to *nil*. To what extent sanatorium treatment has reduced the death-rate from tuberculosis in Denmark it is impossible to say, as no satisfactory comparison has yet been made between the results obtained by sanatorium and the older methods of treatment. The result of a careful inquiry showed that at the close of 1910 3037 patients had undergone sanatorium treatment at different periods during the past decade, and that 1358 of these were still fit for a full day's work.

RARE CONTRACTED PELVES AND CÆSAREAN SECTION.

NEARLY 40 years ago the late Dr. G. E. Yarrow, of Finsbury, contributed to THE LANCET a report of a Cæsarean section which he performed on a rachitic dwarf, 4 ft. 2 in. in height.[1] The child was saved, but the mother died. As stated in Dr. Yarrow's original report the pelvis was preserved and presented to the Obstetrical Society of London. The collection of pelves, once the property of that society, has been recently acquired by the Royal College of Surgeons of England. It includes the Yarrow pelvis which has been

[1] Report of a Case of Cæsarean Section, THE LANCET, Oct. 12th, 1872, p. 523.

carefully examined in the College Museum. A rare type of malformation has in consequence been detected. The lateral mass of the first sacral vertebra is replaced by a transverse process in form like the same process in the fifth lumbar. This deformity would be termed "left-sided lumbar assimilation" by Bayer in his standard work "Das Becken und seine Anomalieen." Symmetrical development of a separate transverse process of the lumbar type in the first sacral makes a "low assimilation pelvis," and symmetrical fusion of the transverse processes of the fifth lumbar into the lateral masses of the first sacral constitutes a "high assimilation pelvis," whilst asymmetrical sacral assimilation of the fifth lumbar has been observed. Unilateral "assimilation" of the first sacral vertebra, as existing in the Yarrow pelvis, causes slight obliquity and narrowing of the inlet, as Whitridge Williams and others have shown. In Dr. Yarrow's specimen, however, the obliquity is but slight, especially as compared with the rare yet well-known Nägele's pelvis, where early ankylosis of the sacro-iliac joint on one side involves defective development of the corresponding os innominatum. The College also possesses a pelvis showing extreme deformity due to mollities, which disease developed in a woman who had previously given birth to several children with ease. Dr. Broughton of Preston performed Cæsarean section, but, as in Yarrow's case, the child only was saved. This pelvis is being re-examined specially with a view of ascertaining by comparison with specimens of mollities in other collections whether there be a distinct mollities or osteomalacia of pregnancy. The disease certainly develops quite independently of gestation, and may be associated with true rachitis; the annals of Cæsarean section, as collected by Radford and Amand Routh, throw some light on this subject, but more is to be desired. Under the direction of the Museum Committee of the College a collection of female pelves illustrating deformities more or less liable to obstruct labour is in course of preparation. The series, including Yarrow and Broughton's specimens, will be added to the College Museum. It is an excellent thing that the College authorities should thus recognise the absolute need of a standard collection of obstetric pelves. Should any readers of THE LANCET possess specimens of malformed female pelves which they may feel inclined to present to the College such specimens will be gratefully received and duly acknowledged by the conservator, Dr. A. Keith.

WE congratulate Miss Eleanor Davies-Colley as the first woman to attain the distinction of becoming a Fellow of the Royal College of Surgeons of England. Her father, the late Mr. J. N. Davies-Colley, was a member of the Council and of the Court of Examiners of the College, and two of her brothers are Fellows. Her grandfather was also a medical man.

Dr. Bernard Hudson has been appointed His Majesty's Consul at Davos.

TYPHOID FEVER IN LEICESTER.—During the month of December an epidemic of typhoid fever has taken place in Leicester, the number of patients admitted to the isolation hospital during that month being greater than during the whole of the previous 11 months of the year. Special inquiries have been made by the medical officer of health of the borough (Dr. C. Killick Millard), and he has ascertained that in practically all the cases the patients admit the consumption of mussels in a raw state. A special report has been prepared for the Leicester sanitary committee, and this has been forwarded to the Local Government Board.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns, having an estimated population of 16,157,797 persons in the middle of this year, 7539 births and 5083 deaths were registered during the week ending Dec. 16th. The annual rate of mortality in these towns, which had been 14·2, 15·7, and 15·2 in the three preceding weeks, rose to 16·4 per 1000 in the week under notice. During the first eleven weeks of the current quarter the mean annual rate of mortality in these towns averaged 14·5 per 1000, and was 0·4 per 1000 above that recorded in London during the same period. The annual death-rates in the 77 towns in the week under notice ranged from 6·0 in Hastings, 6·7 in Walthamstow, 7·7 in King's Norton, and 8·0 in Tynemouth, to 22·5 in Liverpool, 22·8 in West Hartlepool, 23·1 in St. Helens, and 25·2 in Warrington. The 5083 deaths from all causes in the 77 towns were 365 in excess of the number in the previous week, and included 305 which were referred to the principal epidemic diseases, against 276 and 238 in the two preceding weeks. Of these 305 deaths, 71 resulted from measles, 68 from infantile diarrhœa, 64 from diphtheria, 53 from whooping-cough, 27 from scarlet fever, and 22 from enteric fever, but not one from small-pox. The mean annual death-rate from these epidemic diseases was equal to 1·0 per 1000, against 0·9 and 0·8 in the two preceding weeks. The deaths attributed to measles, which had been 44, 66, and 52 in the three preceding weeks, rose to 71 in the week under notice, and caused the highest annual death-rates of 1·4 in Stockport and in Warrington, 1·5 in Smethwick, 1·9 in York, 2·0 in Bournemouth, 2·6 in Norwich, and 3·9 in Burnley. The deaths referred to infantile diarrhœal diseases which had continuously declined from 2714 to 45 in the 16 preceding weeks, rose to 68 in the week under notice, and of these 24 were recorded in London and its suburban districts, 6 in Liverpool, and 3 in Leicester. The fatal cases of diphtheria, which had been 61, 57, and 60 in the three preceding weeks, rose to 64 during the week, and included 17 in London and its suburban districts, 4 in Portsmouth, and 3 each in Plymouth, Derby, Liverpool, Huddersfield, Bradford, and Leeds. The deaths assigned to whooping-cough, which had steadily risen from 16 to 45 in the six preceding weeks, further rose to 53 in the week under notice; 9 deaths occurred in London, 6 in Walsall, 4 each in Birmingham, St. Helens, and Sunderland, 3 in Manchester, and 3 in Sheffield. The deaths referred to scarlet fever, which had declined from 29 to 16 in the three preceding weeks, rose again to 27 during the week, and included 5 in London, 3 in Liverpool, and 2 each in Birmingham, Sheffield, and Rhondda. Of the 22 fatal cases of enteric fever, which were equal to the average number recorded in the five preceding weeks, 5 were registered in London, 2 in West Ham, and 2 in Bradford. The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had decreased from 2213 to 2089 in the four preceding weeks, had further declined to 2042 on Saturday, Dec. 16th; 224 new cases of this disease were admitted to these hospitals during the week, against 203, 248, and 241 in the three preceding weeks. These hospitals also contained on Saturday, Dec. 16th, 1356 cases of diphtheria, 211 of whooping- cough, 91 of measles, and 77 of enteric fever, but not one of small-pox. The 1391 deaths from all causes in London in the week under notice were 152 in excess of the number in the previous week, and included 389 which were referred to diseases of the respiratory system, against numbers steadily increasing from 170 to 331 in the six preceding weeks. The deaths attributed to different forms of violence in the 77 towns, which had increased from 158 to 201 in the three preceding weeks, declined to 195 during the week, and 480 inquest cases were registered. The causes of 39, or 0·8 per cent., of the deaths registered in the 77 towns in the week under notice were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Manchester, Leeds, Bristol, West Ham, Bradford, Hull, Newcastle-on-Tyne, Salford, and in 49 other smaller towns. The 39 uncertified causes

of death included 6 in Birmingham, 5 in Liverpool, 3 in St. Helens, and 3 in Middlesbrough.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns, having an estimated population of 1,710,291 persons in the middle of this year, 789 births and 587 deaths were registered during the week ending Dec. 16th. The annual rate of mortality in these towns, which had been 18·0 and 16·8 in the two preceding weeks, rose to 17·9 per 1000 in the week under notice. During the first eleven weeks of the current quarter the mean annual death-rate in these Scotch towns averaged 16·8, and was 2·3 per 1000 above the mean rate during the same period in the large English towns. The annual death-rates in the several Scotch towns in the week under notice ranged from 7·3 and 15·1 in Perth and Edinburgh to 19·9 in Dundee and 21·4 in Aberdeen. The 587 deaths from all causes were 37 in excess of the number in the previous week, and included 59 which were referred to the principal epidemic diseases, against 72 and 58 in the two preceding weeks; of these 59 deaths, 32 resulted from measles, 8 from whooping-cough, 8 from diarrhœal diseases, 6 from diphtheria, 4 from scarlet fever, and 1 from enteric fever, but not one from small-pox. The mean annual death-rate from these epidemic diseases in the eight towns in the week under notice was equal to 1·8, and was 0·8 per 1000 above the mean rate from the same diseases in the 77 large English towns. The deaths referred to measles, which had been 23, 31, and 23 in the three preceding weeks, rose to 32 during the week, and included 18 in Glasgow and 13 in Aberdeen. The deaths attributed to whooping-cough, which had been 6 and 10 in the two preceding weeks, were 8 in the week under notice, of which number 4 were registered in Aberdeen and 2 in Glasgow. The deaths assigned to diarrhœal diseases, which had continuously declined from 19 to 9 in the four preceding weeks, further fell to 8, all but one of which related to infants under two years of age, and included 5 in Glasgow. The fatal cases of diphtheria, which had been 15 and 8 in the two preceding weeks, further declined to 6 during the week, of which 4 were recorded in Glasgow. The 4 deaths referred to scarlet fever were equal to the average in the four preceding weeks and included 2 in Aberdeen. The fatal case of enteric fever was registered in Glasgow. The deaths referred to diseases of the respiratory system, which had been 113, 113, and 122 in the three preceding weeks, further rose to 126 in the week under notice, and were 4 above the number recorded in the corresponding week of last year. Of the 587 deaths from all causes in the Scotch towns during the week, 164, or 28 per cent., were recorded in public institutions, and 20 were attributed to different forms of violence. The causes of 15, or 2·6 per cent., of the deaths in the eight towns in the week under notice were not certified or not specified; in the 77 large English towns the proportion of uncertified causes did not exceed 0·8 per cent.

HEALTH OF IRISH TOWNS.

In the 22 town districts of Ireland, having an estimated population of 1,149,495 persons in the middle of this year, 615 births and 461 deaths were registered during the week ending Dec. 16th. The annual rate of mortality in these towns, which had been 18·3 and 17·7 in the two previous weeks, rose to 20·9 per 1000 in the week under notice. During the first 11 weeks of the current quarter the mean annual rate of mortality in these towns averaged 18·5 per 1000; in the 77 large English towns the mean annual death-rate during the same period did not exceed 14·5, while in the eight Scotch towns it was equal to 16·8 per 1000. The annual death-rate during the week was equal to 22·0 in Dublin (against 16·0 in London), 20·5 in Belfast, 35·4 in Cork, 11·5 in Londonderry, 21·7 in Limerick, and 22·8 in Waterford; while in the 16 smallest of these Irish towns the death-rate for the week did not exceed 14·8 per 1000. The 461 deaths from all causes were 70 in excess of the number in the previous week, and included 35 which were referred to the principal epidemic diseases, against numbers declining from 47 to 25 in the four preceding weeks; of these 35 deaths, 11 resulted from diarrhœal diseases, 7 from measles, 6 from whooping-cough, 5 from diphtheria, 3 from enteric fever, and 3 from scarlet fever, but not one from small-pox. These 35 deaths from the principal epidemic diseases were equal to an annual death-rate of 1·6 per 1000; in the 77 English towns during the week under notice the mean annual death-rate from these diseases did not exceed 1·0 per 1000; while in the eight Scotch towns it was equal to 1·8. The deaths attributed to diarrhœal diseases, which had been 19, 14, and 7 in the three preceding weeks, rose to 11 during the week, all of which related to infants under two years of age, and included 3 in Dublin, 2 in Belfast, and 2 in Cork. The deaths referred to measles, which had been 4 and 2 in the two preceding weeks, rose to 7 in the week under notice, and comprised 5 in Dublin and 2 in Cork. The fatal cases of whooping-cough, which had been 11 and 6 in the two preceding weeks, were again 6 in the week under notice, of which 3 were recorded in Dublin and 3 in Belfast. The 5 deaths referred to diphtheria, which comprised 4 in Dublin and 1 in Belfast, were equal to the average in the two preceding weeks. The 3 fatal cases of scarlet fever were also equal to the average in the two preceding weeks, and included 2 in Belfast. The 3 deaths from enteric fever, which were slightly in excess of recent weekly numbers, were all recorded in Dublin. The deaths referred to diseases of the respiratory system, which had been 78, 77, and 92 in the three preceding weeks, further rose to 105 during the week. Of the 461 deaths from all causes in the Irish towns in the week under notice, 135, or 29 per cent., were recorded in public institutions, and 9 were attributed to different forms of violence. The causes of 21, or 4·5 per cent., of the deaths in the 22 towns during the week were not certified either by a registered medical practitioner or by a coroner after inquest; the proportion of uncertified causes in the week under notice did not exceed 0·8 per cent. in the 77 English towns, but was equal to 2·6 per cent. in the eight Scotch towns.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Fleet-Surgeons: H. W. Gordon-Green to the *Collingwood*; E. R. Dimsey to the *President*, additional, for three months' hospital course; J. D. Hughes to the *St. Vincent*; and H. B. Marriott to the *Cornwall*, on recommissioning. Staff-Surgeons: R. H. Atkins to the *Pathfinder*; A. W. Iredell to the *Victory*, additional, for disposal; R. W. B. Hall to the *Active*, on commissioning; and R. R. Horley to the *Prince of Wales*. Surgeons: E. L. Markham to the *King Edward VII.*, additional, for Nore Sub-Division, Home Fleet; A. G. V. French to Haslar Hospital; G. T. Verry to the *Victory*, additional, for disposal, and for long P.T. course; and B. Pick to the *Cornwall*, on recommissioning.

TERRITORIAL FORCE.

Royal Army Medical Corps.

3rd London (City of London) Field Ambulance, Royal Army Medical Corps: Cecil William Rowntree to be Lieutenant (dated Nov. 18th, 1911).

1st Western General Hospital, Royal Army Medical Corps: Keith Waldegrave Monsarrat (late Surgeon-Captain, 5th Battalion, The King's (Liverpool Regiment)), to be Captain (dated Dec. 23rd, 1911).

Attached to Units other than Medical Units.—Lieutenant George M. A. Thomas to be Captain (dated Oct. 23rd, 1911). Captain Edward Gray to be Major (dated Nov. 27th, 1911). Lieutenant-Colonel and Honorary Surgeon-Colonel William H. Packer resigns his commission, and is granted permission to retain his rank and to wear the prescribed uniform (dated Dec. 23rd, 1911).

For Attachment to Units other than Medical Units.—Geoffrey Seccombe Hett to be Lieutenant (dated Nov. 1st, 1911).

ROYAL SUSSEX COUNTY HOSPITAL.—Thanks to the generosity of Mr. Charles Borradaile, vice-chairman and ex-president, every ward at the Royal Sussex County Hospital at Brighton has just been equipped with new bedsteads of the latest hospital pattern.

"Audi alteram partem."

THE NATIONAL INSURANCE ACT.

To the Editor of THE LANCET.

SIR,—Notwithstanding all that has been written and spoken about the National Insurance Bill it is doubtful whether many medical men had given much personal thought to its medical aspects before the measure received Royal Assent a few days ago. The members of the profession were aware that the British Medical Association, through its recognised authorities, had adversely criticised certain provisions in the Bill and was endeavouring to amend them so as not only to secure conditions acceptable to the profession but also to safeguard the prescriptive rights and the vested interest of medical practitioners. It is now believed by many thousands of medical men that these endeavours have failed; and they are profoundly disappointed and dissatisfied.

Though late, it may not be too late to consider the principle underlying the question of the medical benefits provided by the Act.

The Act seeks to effect the insurance of many millions of men and women of all sorts and conditions; workers in many and different trades and in occupations of great diversity of effort, skill, and risk, and persons of every state of physical health and vitality, and of various standards of morality. Many of these persons will be genuine workers, of good health and good habits, industrious, sober, thrifty. But a large number will belong to the proletariat who form the fringe of society and are without a definite calling and are too often not only diseased but of depraved habits and of low morals.

Hitherto the principle of insurance has been applied either to carefully selected lives or to small sections of the community whose vital, social, and economic conditions are more or less understood. In the National Insurance Act there is no selection, no discrimination, no gradation. Good lives and bad lives, the virtuous and the vicious, the thrifty and the improvident, the strong and the weak, are lumped together. Not only does this place those who are insured under very unequal terms, the good lives paying for the bad, but it inflicts positive injustice on the members of the medical profession by requiring them to render services indiscriminately at a fixed rate of payment that is barely remunerative even when restricted to specially picked lives.

Medical practitioners have reasonable grounds of objection to such a proposal, and resent the implicit autocratic dictation of the Act. Moreover, no compensation is provided by the Act for the inevitable depreciation in the selling value of a practice, and there is no appreciation of the disturbance which the Act will cause in the existing status of medical men, and in the relations of medical men to one another and to their patients. The Act also ignores—wilfully, perhaps—the fact that in the case of thousands of practitioners, especially those in the smaller towns, their private *clientèle* will be practically wiped out.

Medical men are the only class in the community whom it is attempted to exploit in this way. Lawyers, purveyors of food and fuel and clothing are not placed under any restriction or limitation or supervision as to what they shall charge for their services or commodities to those who come within the provisions of the Act. Perhaps this is reserved.

Unless, therefore, the members of the profession hold together and present a solid and united front, helping each other and bearing each others' burdens, there is a grave risk that the pressure of circumstances may be too great for some of the weaker brethren, who may find themselves compelled, unwillingly perhaps, to accept the poor rate of remuneration and the humiliating terms of service which the Act offers. Or what may be a greater evil, the Act will tend to bureaucratise the profession and introduce a class of "whole-timers" who will thereby become State functionaries, and be able by their subsidies to engage in an unfair and ruinous competition with free practitioners, to whom will remain in many cases only a small fragment of the community from which to draw patients.

Further, the Act abrogates the tacit agreement of the State that those who have devoted time and money and thought to the acquisition of professional knowledge and skill, and who have secured a legal right to practise, shall be entitled to free use and enjoyment in the disposal of their possessions. Further, it will check honourable rivalry of skill and talent, which always benefits the public; it will withdraw the stimulus to high endeavour, and will ultimately degrade the status of the profession of medicine by withholding the prospect of reasonable recompense for the large outlay necessary for a full and complete medical training.

Such a consummation would ultimately injure the whole community. If the profession should fail to attract the best class of men the standard of knowledge and skill will decline to the detriment and danger of public health and safety.

With such grave issues at stake it was scarcely prudent to negotiate about details such as rates and methods of remuneration, and terms of service, &c. It would have been wiser to stick to principles.

Granting, for the sake of argument, that the motive underlying the National Insurance Act is well-intentioned, we cannot close our eyes to the fact that the Bill was not allowed free and impartial discussion, but was forced through the House of Commons by methods which violated the best traditions of Parliamentary procedure; that one of the great political parties—the largest in numbers and the most homogeneous in character—repudiated all responsibility for the Act, and that the House of Lords refused any reasoned consideration of the Bill.

Although personally I do not regard the so-called "six cardinal points" as sufficient in themselves, we have pledged ourselves to them and should abide by them. But they should be the irreducible minimum and should be clearly provided for without the possibility of cavil or equivocation.

If these "points" are rejected or evaded, then the profession is free either to refuse to do any work under the Act or to negotiate afresh.

Should fresh negotiations become practicable I would venture to suggest that whatever other protecting precautions may be taken the profession should insist that all payment for medical services under the Act should be for work done, and not on any system of capitation, which would not only perpetuate but aggravate the evils of contract practice.

I am, Sir, yours faithfully,

Dec. 26th, 1911. J. TWEEDY.

To the Editor of THE LANCET.

SIR,—The question whether the Council of the British Medical Association has or has not failed in its duty to the members of the Association will, I understand, be dealt with at a special general meeting to be held at an early date. In regard to this matter I desire to direct attention to a few facts which hitherto have not received the publicity they deserve.

Whenever a member of the Council speaks at a meeting or writes in the press in defence of the recent negotiations, we always hear the same remark—"The Representative meeting of Nov. 23rd and 24th authorised us by its resolutions to go on negotiating with the Government, and we have simply followed instructions." Now it can be shown that this so-called "Representative" meeting was conducted by the two gentlemen who successively occupied the chair (Dr. Maclean and Dr. Buist) in such a way that it was not representative in character, and this being so the Council's defence is gone.

In proof of my assertion I shall deal first with a remark made by Dr. Maclean. At an early stage of the proceedings he told the representatives that they were free to vote as they thought fit, and that they were not bound by the terms of the resolutions passed by their divisions. I desire to draw particular attention to the fact that all reference to this remark was omitted from the otherwise full account of the meeting published in the *British Medical Journal* Supplement of Nov. 25th. I wish also to point out that in the correspondence reprinted from the *Scotsman* in the Supplement of Dec. 23rd Dr. Maclean and Dr. Macdonald in their joint letter avoided dealing with this point, which had been specially raised by Dr. William Craig, and contented themselves with saying "We do not propose to follow Dr. Craig in his criticism of the internal proceedings of the Representative meeting, as

we do not consider your columns a suitable place for such a discussion." I fancy many of us will agree with Dr. Maclean and Dr. Macdonald that there is a better place than the *Scotsman* columns for dealing with the matter, and will look forward instead to a ventilation of the subject at the forthcoming special general meeting. Again, I would draw attention to the fact that though the remark of Dr. Maclean with which I am dealing was quoted by Mr. Pinder in his speech at the Queen's Hall meeting on Dec. 19th, this reference was suppressed from the report in the *British Medical Journal* Supplement of Dec. 23rd; it will, however, be found recorded in other accounts of the meeting—for example, in the report given in the *Medical Press and Circular* dated Dec. 20th. So far from Dr. Maclean's ruling as to the representatives' freedom in voting being a correct one, it has been condemned by everyone I have spoken to regarding it, and there can be no doubt as to the view any one of the divisions would have taken had its representative inquired, prior to the meeting, "Am I or am I not bound in my voting by the terms of your resolutions?" This particular Representative meeting was a momentous one at which a very grave decision had to be made—a decision whether we would go on negotiating or would say, "No, this is not the Bill for us," and I maintain that for Dr. Maclean to influence the meeting in its voting, as it undoubtedly was influenced, was a gross abuse of his position as chairman. I say, further, that the three examples which I have given of suppression of his remark—firstly in the *British Medical Journal* report of the meeting, secondly in the *Scotsman* correspondence, and thirdly in the *British Medical Journal* report of the Queen's Hall meeting—strongly suggest that the Council is none too anxious for Dr. Maclean's statement to have the publicity which I for one am determined it shall receive. I am not aware of any rule or by-law of the Association giving the representatives freedom to vote in a direction contrary to the definite instructions of their divisions. If such a rule does exist, I think the body of the profession will be with me in agreeing that the sooner it is rescinded the better.

The next point to which I wish to direct attention is this. The "Representative" meeting was most certainly swayed and directed by the special pleading of members of the Council, who managed to get certain resolutions and amendments passed, and thus caused others to be ruled out of order as incompatible with those already secured. The result was that a large number of the really important resolutions which had been sent up by various divisions—resolutions to break off negotiations, to refuse to work under the Bill, and so forth—had no chance of discussion at all, but were merely mentioned to be withdrawn from the meeting. The representatives found their time being frittered away instead in useless discussions, such as whether they should demand three, five, or eight members on a committee of 80, just as if it were not obvious that in any case their representatives on such a committee would be in a quite helpless minority. I say unhesitatingly that no onlooker at that meeting would have thought for a moment that the members of the Council were there as *our* representatives to carry out *our* instructions, but on the contrary he would certainly have taken the Council to be holding a brief for the Government as against ourselves. I myself (present as an onlooker) noticed many expressions of indignation at the way the meeting was carried on.

I have also to mention the Council's recommendation in the matter of Mr. Smith Whitaker's appointment. At the "Representative" meeting a member rose and said there were rumours in the smoke-rooms of clubs and elsewhere that a high appointment under the Bill had been offered to an official of the British Medical Association, and he proposed a resolution that no member of the Association should take any post under the Bill without the consent of the Association. In dealing with this matter Dr. Maclean said in effect that, speaking for himself, if any such post were offered him his answer would be irrevocable; that he much preferred to continue to work for the Association in the future as he had worked in the past, and that, as to the smoke-room rumour, it was best left in the smoke, where it had been found. These remarks by Dr. Maclean undoubtedly influenced the meeting greatly. The representatives cheered loudly, and obviously accepted the statement as an assurance that any rumours were unfounded. They felt that any distrust they might have had in the Council had not been merited, and that they might safely trust the Council to continue negotiations. It is now clear that the subject of Mr. Smith Whitaker's appointment was deliberately concealed from the meeting. Dr. Maclean has said he considered that at the time of the Representative meeting the matter had dropped. But, if so, surely he should have told the meeting, "There has been an offer but it has been declined, and the matter is considered dropped." If, on the other hand, he did not consider the matter dropped it was equally his duty to tell the meeting "There has been an offer." At a divisional meeting held at the Battersea town-hall on Dec. 13th I moved a resolution calling upon the Council to resign. Dr. Lauriston Shaw, who had been invited to attend the meeting, spoke in defence of the Council, and said that Dr. Maclean could not have told the Representative meeting what was going on as the matter was confidential. But surely there would have been no breach of confidence in making a general statement, mentioning no names, that there had been an offer from the Government. And, as a matter of fact, Dr. Maclean, in replying to Dr. Major Greenwood at the Council's meeting of Dec. 2nd, did not claim anything on the ground of the matter being confidential. He simply said that at the time of the Representative meeting "the declension of the Medical Secretary to accept the offer controlled the position."[1] It is clear, then, that the Chancellor's offer was deliberately concealed from the meeting without any justification. Can anyone doubt that had the representatives known what was going on they would have passed very different resolutions?

I repeat that the Council has acted as if it held a brief for the Government, and this at a time when the aims of the Government and of ourselves are, as most of us are convinced, in hopeless antagonism. In trying to solve the problem how it comes about that the very men whom we have ourselves chosen have been acting against us I can only imagine that the members of the Council were so gratified to find themselves hob-nobbing with Cabinet Ministers and receiving the smiles and flattery of the Chancellor of the Exchequer that they forgot all about those 20,000 men who had placed their faith in them, and whose interests had been entrusted to their care.

I am not now attempting to discuss the ultimate effect of the Act upon our profession and upon the public welfare, though the vast extension of contract practice which is contemplated seems to an overwhelming majority of us to be a disastrous move from all points of view, and most of us are firmly of opinion that the medical provisions of the Act should be dropped. This letter is simply the result of a very strong feeling that we have not had the fair-play and straightforward dealing which we had a right to expect from the Council. That body committed, to say the least, a grave error of judgment when it conducted that "Representative" meeting in such a way as to induce it to pass a resolution authorising the continuance of negotiations. I for one look forward to the appointment of a new Council which shall be truly representative of the members of the Association.

I must apologise for the length of this letter, but the points dealt with seem to me of considerable importance at the present juncture, and this must be my excuse.

I am, Sir, yours faithfully,

EDWIN SMITH, M.D. Lond.,
Barrister-at-Law.

London, S.W., Dec. 26th, 1911.

To the Editor of THE LANCET.

SIR,—This is an appeal to refuse work under the Insurance Act, for the following reasons:—

1. That the six cardinal points originally formulated by the British Medical Association have not been conceded and no assurance has been given by Parliament that they ever will be conceded.

2. That the majority of the divisions of the British Medical Association passed resolutions in the following terms previous to the Representative meeting held Nov. 24th, 1911: "That unless the six cardinal points were embodied in the Bill we should refuse to undertake any duties under the Bill."

3. That our minimum requirements have not been embodied

[1] See Supplement, Dec. 9th, p. 587.

in the Act in statutory form after months of negotiations and the expenditure of a large sum of money; therefore it follows we should refuse all work under the Act.

4. That the "Wait and See" policy of the Council of the British Medical Association is not the wisest policy for the profession to adopt. First, their policy for "collective local bargaining" will lead to disunion of the profession and endless wrangling. To bargain effectually we must bargain on equal terms. Our position to bargain under this Act is three medical men in a committee of 40 (minimum), three in a committee of 80 (maximum). Second, is it a professional way of behaving to bargain and wrangle for fees before a Local Health Committee? It must be remembered that the Local Medical Committees have no statutory powers, and, knowing what representation we have on the Local Health Committees, what chance can we possibly have of forcing the demands of the Local Medical Committees?

5. That the Act promises adequate medical attendance to 15,000,000 people probably under the worst form of contract practice. For the sum of money provided for the medical part of the Act is £4,500,000 only, and no mention has ever been made as to the amount of work or the remuneration —including payment for consultations, anæsthetics, night visits, mileage, minor operations, vaccines, antitoxins, certificates, &c. No mention is made as to hospital treatment for the insured.

6. That taking everything into consideration regarding the Act, and knowing that all our negotiations have failed to get our minimum demands, would it not be much more dignified for us as a profession to refuse at once to work under the Act, and to straightway inform "the State" that if they want the medical profession to work the Act they must come *to us* with their terms? We can then consider whether they are good enough for us to accept or not.

I am, Sir, yours faithfully,

H. J. GODWIN,

Dec. 27th, 1911. Hon. Secretary, Winchester Division B.M.A.

SOME POINTS IN THE TREATMENT OF PULMONARY TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—I note that no one has made any comment on my letter in THE LANCET of Sept. 2nd, 1911, p. 723. Dr. Camac Wilkinson has never made the least attempt to answer the letter which I wrote commenting on one of his to the *British Medical Journal* a few months since. In America tuberculin appears to be given the same way as I am at present giving it here. No one has any right to administer tuberculin until he has had the patient under supervision in bed for a period, and no one is justified in giving tuberculin without taking a rectal temperature before rising in the morning.

It is unfortunate that neither Dr. Wilkinson nor his opponents take proper precautions to see whether or not they are doing good when giving tuberculin. There is no doubt that tuberculin is a useful adjunct in treating suitable cases of phthisis, and it may be necessary to the cure of some persons. Unfortunately, its limitations are very great, and in some apparently suitable cases it does a great deal of harm.

I have noticed that cases in which there is a well-marked local reaction to an injection of tuberculin have relatively a favourable prognosis. I am of opinion that the swelling at the seat of injection produces in the healthy tissues at the site of injection an anti-tuberculin which is bactericidal. I cannot account otherwise for a fall in temperature apparently preceded by no negative phase.

One thing is, I think, clear, and that is that Dr. Wilkinson does not rightly understand the problem he is attacking; and another is that we have by no means learnt the correct way of giving tuberculin. However, the more care that is taken in giving tuberculin the less disastrous, and the more beneficial, will be the results. It is unnecessary, it seems to me, to put forward tuberculin as a specific when at present, at least, it is but an uncertain adjunct. Were the remedy considered apart from its results it would be surprising, indeed, if it were accepted as being what many of its sanguine exponents would have us believe. The fact that it *may* be useful is the reason for its having such a hold on persons who have never had the opportunity of studying phthisis either on themselves or on others under their constant care. I notice a growing tendency to publish the results of treatment when the after-history extends to only a few weeks or months. This is, of course, ridiculous with regard to phthisis. There is certainly such a thing as auto-inoculation, though some doubt now appears to be cast on this; it occurs most frequently after movements of the diseased focus. This auto-inoculation, however, probably ceases soon after the temperature has become normal, and a great deal of exercise can be indulged in after the disease has become quiescent without producing auto-inoculation. In many cases of pulmonary tuberculosis starting with hæmoptysis auto-inoculation is probably impossible by violent exertion. It is as well to remember that a fresh spread of the disease is not correctly described as auto-inoculation, and yet this is often what people really mean when they talk of auto-inoculation. Of course, this spread may directly result from too large an auto-intoxication. If tuberculin and exercise are taken at the same time it is probably much easier to produce an auto-inoculation.

It may be said that (*a*) No one can be said to be cured of pulmonary tuberculosis who is capable of auto-inoculation; (*b*) a chronic case may be very difficult to auto-inoculate and yet not be cured. It is doubtful whether the mere tolerance of the body generally for tuberculin can be regarded as a cure. Indeed, I am not sure but what after such tolerance has been established it does not become impossible to cure the patient. Something in the tissues appears to be used up which is necessary for a cure.

I am, Sir, yours faithfully,

EDWARD E. PREST.

Ayrshire Sanatorium, New Cumnock, Dec. 18th, 1911.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Surgical Disinfection of the Skin by Means of Alcohol.

As long ago as 1887 Fürbringer endeavoured to show that alcohol was a satisfactory disinfectant for the skin of the hands, but at a subsequent period the results of experimental work were published tending to prove that the application of soap was insufficient. According to general opinion at the present time alcohol has hardly any antiseptic properties. M. Marquis has, however, taken a different view in a report written by him and read by M. Savariaud at a recent meeting of the Surgical Society, giving statistical details of 50 operations in which there was healing by primary union without stitch suppuration. After treatment of the skin of the hands with alcohol for a period varying from four to ten minutes no microbial product was found in the epidermis. It was stated that 15 experiments were made in which a preliminary infection of the skin was followed by washing for ten minutes and drying by free exposure to the air for two minutes, the result being that in 10 of these cases no colonies were found. Rinsing was not so effective as rubbing with a sterilised compress. The hands remained sterile for 20 or 30 minutes. Sections of the skin after treatment with alcohol did not show any microbial lesion.

Advantages of Classical Study for Medical Practitioners.

Of late years several alterations have been made in the programmes of study in France, and as happens with all reforms these alterations have found supporters on one hand and a great number of opponents on the other. The latter include all those who hold that the studies known as "the humanities" are an essential instrument of mental culture. This question has been quite recently discussed from a medical point of view by Dr. Laignet Lavastine at a meeting of the Société de l'Internat des Hôpitaux de Paris. His discourse had a threefold division, showing successively how it has come about that the utility of classical studies for medical practitioners was called in question at the present day; how the objections that have been raised against such studies on the ground both of principle and of actual fact might be met; and, in the third place, how evident it was that such studies, instead of being eliminated from medical education, ought rather to be obligatory as advantageous to society, to patients, and to practitioners. He said that the decline of classical culture among young medical men dated from the

year 1902, when holders of the Bachelor Degree without Latin and Greek began to be admitted to the Faculty of Medicine equally with bachelors who had passed in Latin and Greek. Other causes of the deterioration of the general culture of young medical men were the inefficient teaching of languages both living and dead, too early specialisation, and the encyclopædic but superficial cramming which was given to them nowadays.

Murderous Attack on a Medical Man.

Dr. Lepers, of Roubaix, has recently been the victim of an attack in which he was wounded in the hand and the head as he was leaving a house where he had been attending a child. The motive of the crime remains unexplained.

Suspension of Lectures on Anatomy.

The medical students in Paris are at present greatly excited by recent occurrences at the Faculty. As a result of the disturbances which, as I have already mentioned, took place in the classroom of Professor Nicolas, steps were taken by Professor Landouzy, the dean, to prevent repetition of these disorders, and he accordingly directed that the amphitheatre where the lectures were delivered should be occupied by municipal guards and police officers. Here, however, there was now no disturbance, for the students, changing their tactics, arranged among themselves to surround the laboratory of Professor Nicolas in such numbers that they literally blockaded him in his laboratory and prevented him from coming out. Seeing that they could not be pacified, Professor Landouzy reported the circumstances to the vice-rector of the Academy of Paris, whereupon M. Liard issued an edict suspending until further orders the anatomical lectures of the Faculty of Medicine and the courses of practical instruction connected therewith. On the other hand, the old pupils of Professor Nicolas in Nancy have sent him an address expressive of their respectful sympathy with him in his present difficulties. Naturally enough, the students feel themselves seriously affected by the rector's decision, and they have held meetings for the purpose of considering how they may be able to get it withdrawn.

Fracture of the Cervical Spine through Diving.

The question of the fracture of the cervical spine through diving has been raised by M. Lejars, speaking on behalf of Dr. Lecoq of the army medical service. Dr. Lecoq had reported the case of a soldier who on diving into the sea struck the bottom at a depth of one metre. He lost consciousness, and on examination was found to have a wound on the top of his head as well as complete paralysis of the lower limbs, partial paralysis of the upper limbs, complete anæsthesia of the abdominal wall, and partial anæsthesia of the upper limbs. The diaphragm acted, but respiration was slow and difficult. In the back of the neck and in the pharynx there was a painful spot without deformity. A fixation apparatus was applied. The same evening his temperature rose to 40° C., and the patient died 73 hours after the accident. The second case being of a similar character Dr. Lecoq expressed the opinion that as the nature of the lesions was quite unknown it was advisable not to attempt an operation under such circumstances. On the subject being debated at the Surgical Society M. Routier said that in the case of a man suffering from a similar injury he had attempted reduction of the dislocation, but the patient succumbed; a Japanese, however, who presented the same phenomena of paralysis in consequence of a fall received no surgical treatment and recovered, although remaining somewhat hemiplegic. M. Tuffier, M. Reynier, M. Championnière, and M. Auvray questioned the propriety of an operation. M. Faure said that if there was no deformity he thought that there ought to be no operation, but in the contrary event it was better to operate, because the patient was not made worse by exploring the vertebral column. The principal point was to relieve compression of the spinal cord if it existed, and there was a possibility that the result might be successful, but if the cord was crushed nothing could be done.

French Balneological Congress.

The French congress representing mineral water localities, sea-bathing places, and climatic health resorts has just met in Paris under the presidency of the mayor of Vichy. The congress adopted resolutions to the effect that instruction in hydrology ought to be given in the various faculties of medicine, beginning with the next academical half year; that professorial chairs of hydrology ought to be instituted; and that in towns frequented by visitors in search of health suitable dietary scales should be introduced in the hotels. It was further recommended that the drinking water in balneary and climatic health resorts should be analysed at the commencement and during the course of each season, that a portion of the assessment deducted by the State from the proceeds of the sports and gaming should be devoted to improving the general appearance and hygienic conditions of the place, and that the visitors' tax (*taxe de séjour*) should be in operation next season.

Dec. 23rd.

CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

The Ottoman Red Crescent Society and the War.

THE above society was formed 46 years ago. In consequence, however, of the absolutist *régime* during Abdul Hamid's reign it could do very little good. Its settlement upon a firm scientific basis took place only after the deposition of the ex-Sultan and the establishment of a Constitutional Government. Its present organisation it owes to Madame Rifaat Pasha, the wife of the former Foreign Minister, at present Ottoman Ambassador in Paris. The latest and most useful establishments of the society, due principally to the initiative of that lady, are the following: Three medical and sanitary stations have been erected in the burnt-out quarters of Akserai and Balat, in Stamboul. In each of these quarters a permanent medical service has been established. During the cholera epidemic all the patients received gratuitous treatment, getting, in addition, milk and yaourt free of charge. Prompt prophylactic measures were taken by the society, and the sum of about £700 was expended for disinfectants and various apparatus. Soon after the proclamation of war the Red Crescent Society got to business under the guidance of Dr. Kerim Sebati Bey, professor of the Medical Faculty at Haidar Pasha, and as a result excellent work is now being done at Tripoli, where an ambulance lazaretto is in working order. The outlay for this humanitarian work, amounting to about 5000 Turkish liras, was entirely met from the means of the society. Another staff, consisting of three medical men and five nurses, was sent under Dr. Arif Bey to Benghazi at an expense of 1500 Turkish liras. Already about £8000 have been expended, and as the war will most likely last for some time further considerable expenses will have to be met. The means of the society are beginning to be exhausted and an earnest appeal is made to the Ottoman nation for contributions. The appeal is especially made to the Moslem ladies, who are urged to form committees and sub-committees in different cities of the Ottoman Empire. According to paragraph 43 of the regulations of the society, Turkish women are allowed actively to participate in the work of the society, which is in itself a remarkable sign of progress in Turkey, considering that during the late *régime*—i.e., only three years ago—no Moslem women were ever allowed to overstep the narrow limits of their dull, utterly inactive, harem life.

The Treatment of the Insane.

Constantinople has very little accommodation for insane people. It was expected that with the advent of the Constitution matters would be put right in this direction. This expectation has not been realised, for there were so many other needs demanding immediate attention. The Turks consider a lunatic a sort of saintly personality, who must not be touched and who must enjoy complete freedom. The deplorable occurrences that result from such an attitude can easily be imagined. Of late the police authorities have been trying to accommodate all the insane, who used to roam freely in the streets, but as the asylums are few and far between the lunatics are often confined in the garden of the police administration with no special attention at all. The scenes that take place in this confinement are indeed lamentable. Frequently the police are driven, in self-defence, to have recourse to force. I understand that the municipality

is taking the matter into serious consideration and that new asylums will soon be erected.

The Cholera Epidemic.

Although competent authorities assert that there are no more cholera cases in Constantinople, there can be no doubt that sporadic deaths from this disease still occur. Thus, in the Greek Hospital at Balukli, two women succumbed to it the other day. A few isolated deaths from cholera have also taken place on board the steamers which have arrived here from the seat of war. Precautionary measures are being taken.

Dec. 23rd.

Medical News.

UNIVERSITY OF OXFORD.—In the Congregation held on Dec. 16th the following degrees were conferred:—

D.M.—H. C. G. Semon, Magdalen.

B.M.—J. A. Noble, Queen's; W. J. Pearson and C. J. G. Taylor, University; W. J. Oliver, Oriel; W. W. Wagstaffe, New College; W. H. Bleaden, Brasenose; and T. B. Heaton, Christ Church.

UNIVERSITY OF CAMBRIDGE.—The following candidates passed the Second Examination for medical and surgical degrees, Part I. (Human Anatomy and Physiology):—

J. C. Andrews, St. John's; G. L. Attwater, B.A., Pembroke; L. W. Batten, B.A., Sidney Sussex; G. A. G. Bonser, B.A., St. John's; J. C. Bramwell, Trinity; H. F. Brice-Smith, B.A., St. John's; W. E. H. Bull, B.A., Caius; H. R. Buttery, B.A., Christ's; A. B. Buxton, Trinity; M. Chadwick, B.A., St. John's; G. F. Clifton, B.A., Downing; G. R. E. Colquhoun, Trinity; A. C. M. Coxon, B.A., Magdalen; E. C. Cunnington, B.A., Corpus Christi; E. D. D. Davies, B.A., Christ's; A. N. Drury, Caius; H. Dunkerley, B.A., Downing; H. S. Evans, B.A., Trinity; E. Forrester-Paton and L. S. Fry, B.A., King's; H. A. C. Goodwin, B.A., Jesus; E. H. H. Granger, Clare; C. Grantham-Hill, Caius; W. T. Hare, B.A., Christ's; J. B. Hunter, St. John's; J. H. Jordan, B.A., Emmanuel; H. D. Lander, B.A., Caius; F. C. Lapage, B.A., King's; H. W. Leatham, Trinity; A. H. Little, Corpus Christi; H. D. McCall, B.A., Christ's; E. C. Malden, Caius; R. A. Mansell, Emmanuel; C. G. T. Mosse, Caius; D. F. A. Neilson and W. D. Newcomb, Trinity; W. Oats, B.A., Caius; H. B. Padwick, Emmanuel; H. R. Pollock, B.A., Trinity; S. R. Prall, Emmanuel; W. B. Purchase, B.A., Sidney Sussex; G. D. Read, B.A., St. John's; W. H. C. Romanis, Trinity; T. H. Somervell, Caius; G. E. Spicer, Trinity; and H. N. Stafford, A. R. S. Warden, and E. Watson-Williams, Caius.

At the Third Examination in Part I. (Pathology and Pharmacology) the following were successful:—

M. Avent, B.A., Caius; H. M. McC. Coombs, B.A., Emmanuel; R. Gamlin, M.A., King's; H. K. Griffith, B.A., Trinity; A. N. Hodges, B.A., Queens'; R. M. Miller, M.A., Clare; C. G. H. Moore, B.A., Caius; R. S. Morshead, B.A., Trinity; G. M. Parker, B.A., Emmanuel; C. H. G. Philp, B.A., St. John's; and V. T. P. Webster, B.A., Emmanuel.

ROYAL SANITARY INSTITUTE.—The following members of the medical profession have been elected Fellows of the Institute: Fleet-Surgeon W. E. Home, R.N.; Sir Victor Horsley, F.R.S.; Dr. J. W. Mason, medical officer of health of Hull; Dr. E. M. Smith, medical officer of health of York; Mr. T. H. A. Valintine, chief health officer, Wellington, New Zealand; and Dr. W. H. Willcox.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST.—A communication to the council of this hospital has been made by Dr. D. Barty King, assistant physician to the hospital, of an offer by an anonymous donor of a sum of money to cover the entire cost of rebuilding and enlarging the out-patient department. The new buildings will include a lecture theatre, pathological museum, and research laboratory for clinical instruction and research in diseases of the chest. The gift will amount to over £6000.

KING EDWARD'S HOSPITAL FUND FOR LONDON.—Since the Distribution Committee of King Edward's Hospital Fund for London agreed on its recommendations to the Council with regard to the awards for the current year the following communication has been made to the Fund. In memory of his daughter, the late Mrs. Maud Ashley, Sir Ernest Cassel is giving to hospitals and other kindred institutions the sum of £50,000. Of this sum £7000 is divided between the Romsey Nursing Home, Romsey, Hampshire; the Royal Hants County Hospital, Winchester, Hampshire; the Victoria Hospital, Blackpool, Lancashire; the Fleetwood Cottage Hospital, Fleetwood, Lancashire; the Lytham Cottage Hospital, Lytham, Lancashire; the Royal National Hospital for Consumption and Diseases of the Chest, Ventnor; the Royal Sea Bathing Hospital, Margate; and £31,500 go to King Edward's Hospital Fund for London, on the understanding that it is divided among the institutions which receive grants from the Fund this year in the same proportion as the Fund's grants are divided, thus increasing the distribution of the Fund by one-fifth from £157,500 to £189,000. The remainder has been allocated among various London hospitals, subject to certain conditions.

POST-GRADUATE DEMONSTRATIONS AT THE MANCHESTER ROYAL INFIRMARY.—A clinical demonstration open to all qualified medical practitioners free of charge will be given at the Manchester Royal Infirmary every Monday and Friday at 4.30 P.M. The demonstrations will begin on Monday, Jan. 15th, and will continue throughout the year with the exception of Whit-week and the months of April, August, and September. The demonstrations will be given by members of the honorary medical staff, and the subjects will be found each week in the list of post-graduate lectures in THE LANCET. It is intended as far as possible to devote the Monday demonstrations to subjects of medical, and the Friday demonstrations to subjects of surgical, interest. A notice giving the particulars of each day's demonstration will be posted in the lodge at the main entrance in Oxford-street.

MEDICAL SICKNESS AND ACCIDENT SOCIETY.—The usual monthly meeting of the executive committee of this society was held at 429, Strand, London, W.C., on Dec. 15th. There were present Dr. F. de Havilland Hall (in the chair), Dr. F. C. Martley, Mr. J. Brindley-James, Dr. M. G. Biggs, Mr. F. S. Edwards, Dr. F. J. Allan, Dr. F. S. Palmer, Dr. J. Pickett, Mr. E. Bartlett, Dr. W. Knowsley Sibley, and Dr. J. B. Ball. The sickness experience of the society during the summer and autumn months has been well under the amount expected and provided for, and the financial results of the working of the society for this year bid fair to be exceptionally satisfactory. The number of new entrants has been unusually great, and more members have availed themselves of the power given by the rules to increase their sickness benefits than in any previous 12 months of the society's operations. Prospectus and all further particulars may be obtained on application to Mr. F. Addiscott, secretary, Medical Sickness and Accident Society, 33, Chancery-lane, London, W.C.

THE CHILDREN'S SANATORIUM FOR THE TREATMENT OF PHTHISIS.—On Dec. 19th Mr. Theodore Hamilton Beit performed the ceremony of laying the foundation-stone of the new building of this sanatorium near Holt, Norfolk, the cost of which was chiefly met by the generosity of his father, Mr. Otto Beit. During the present year Queen Alexandra has graciously given her patronage to the institution, and its value has been recognised by King Edward's Hospital Fund. The chairman, the Rev. E. C. Bedford, and others spoke, and a vote of thanks was passed to Mr. Otto Beit for his generous assistance. Whatever may be the effect of the Insurance Act on sanatoriums, it is still most necessary that voluntary help for this important work should not fail. For it must be remembered that although the cost of building has been provided for, it now becomes necessary to augment the maintenance funds in proportion to the increased number of children who will be accommodated when the new building is opened in the coming summer. The secretary is Mr. T. H. Wyatt, M.V.O., 68, Denison House, Vauxhall Bridge-road, London, S.W.

BOOKS, ETC., RECEIVED.

CASSELL AND CO., LIMITED, London.

Letts's Diaries for 1912:—Medical Diary. Space for 54 patients' names daily. Prices 2*s.* 6*d.*, 3*s.* 6*d.*, and 4*s.* Space for 108 patients' names daily. Prices 4*s.*, 5*s.*, and 5*s.* 6*d.*

Nurses' Report Book and Diary. Price 2*s.* net.

Office Diary and Almanac. No. 10. Price 4*s.* 6*d.*

Walker's "Tear-off" Block Calendars for 1912:—Imperial Calendar. Price 1s. 9d. Graphic Calendar. Price 1s.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

ALLNUTT, E. B., M.R.C.S., L.R.C.P. Lond., has been appointed House Physician at Westminster Hospital.

COLLEDGE, LIONEL, F.R.C.S. Eng., has been appointed Honorary Assistant Surgeon to the Throat Hospital, Golden-square.

CORE, WILLIAM, M.B., Ch.B. Edin., has been appointed Junior House Surgeon at the Blackburn and East Lancashire Infirmary.

CUMBERLIDGE, W. I., M.B., B.C. Cantab., F.R.C.S. Eng., has been appointed Honorary Assistant Surgeon to the Leicester Infirmary.

DUNDAS, J., M.B., B.S. Edin., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Ramsgate District of the county of Kent.

FAIRLEY, JAMES, M.D. Glasg., D.P.H., has been appointed Assistant Medical Officer to the Portsmouth Municipal Tuberculin Dispensary.

HAIGH, W. E., F.R.C.S. Eng., L.R.C.P., D.T.M., has been appointed Senior Resident Medical Officer at the General Hospital, Nottingham.

HICKS, J. A. BRAXTON, M.D., B.S. Lond., D.P.H. Camb., has been appointed Clinical Pathologist to the West End Hospital for Nervous Diseases.

MARSHALL, J. COLE, M.D. Lond., F.R.C.S. Eng., has been appointed Ophthalmic Surgeon to the Royal Waterloo Hospital.

PYBUS, FREDERICK, M.S. Durh., F.R.C.S., has been appointed Surgeon to the Hospital for Sick Children, Newcastle-on-Tyne.

WILSON, WILLIAM, M.B., Ch.B. Vict., has been appointed Honorary Assistant Ophthalmic and Aural Surgeon to the Royal Infirmary, Wigan.

ERRATUM.

Under this heading in THE LANCET, Dec. 23rd, page 1817, the appointment of Dr. Oates should read as follows:—

OATES, GEOFFREY EUGENE, M.D. Lond., M.R.C.P. Lond., has been appointed Assistant Medical Officer of Health of Ilford.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BETHNAL GREEN INFIRMARY, Cambridge Heath, E.—Assistant Medical Officer. Salary at rate of £100 per annum, with apartments, board, and washing.

BIRMINGHAM EDUCATION COMMITTEE.—School Medical Officer. Salary £260 per annum.

BRIGHTON PARISH WORKHOUSE INFIRMARY.—Consulting and Operating Surgeon. Salary 50 guineas per annum.

BRIGHTON, ROYAL SUSSEX COUNTY HOSPITAL.—Assistant Pathologist. Salary £100 per annum, with board, residence, and laundry. Also Assistant House Surgeon, unmarried. Salary £80 per annum, with apartments, board, and laundry.

BRISTOL ROYAL INFIRMARY.—Dental House Surgeon. Salary £100 per annum, with apartments, board, and laundry.

BURNLEY, VICTORIA HOSPITAL.—Second House Surgeon for six months. Salary at rate of £80 per annum, with residence, board, and washing.

CANCER HOSPITAL, Fulham-road, London, S.W.—House Surgeon for six months. Salary £70 per annum.

COLCHESTER, ESSEX COUNTY HOSPITAL.—House Surgeon. Salary £80 per annum, with board, washing, and residence.

CROYDON MENTAL HOSPITAL, Upper Warlingham, Surrey.—Pathologist and Third Assistant Medical Officer. Salary £200 per annum, with quarters, board, and laundry.

GERMAN HOSPITAL, Dalston.—Honorary Assistant Physician.

GRIMSBY AND DISTRICT HOSPITAL.—Senior House Surgeon and Assistant House Surgeon. Salaries respectively £100 and £60 per annum, with board, lodging, and washing.

GUILDFORD, ROYAL SURREY COUNTY HOSPITAL.—Assistant House Surgeon. Salary £75 per annum, with board, residence, and laundry.

HOSPITAL FOR DISEASES OF THE THROAT, Golden-square, W.—Resident House Surgeon. Salary £75 per annum, with board, residence, and laundry.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—House Physician, unmarried, for six months. Salary £30, with board and residence. Also Casualty Medical Officer. Salary £200 per annum, with luncheon.

HULL ROYAL INFIRMARY.—Senior Assistant House Surgeon. Salary £100 per annum, with board and lodging. Also Assistant House Surgeon. Salary at rate of £60 per annum, with board and lodging.

ITALIAN HOSPITAL, Queen-square, London, W.C.—Honorary Surgeon. Also Honorary Assistant Surgeon.

KENSINGTON AND FULHAM GENERAL HOSPITAL, Earl's Court, S.W.—Ophthalmic Surgeon.

LARBERT, STIRLING DISTRICT ASYLUM.—Second Assistant Medical Officer. Salary £130 per annum, with board, &c.

LEEDS GENERAL INFIRMARY.—Assistant Clinical Pathologist. Salary £150 per annum.

LEICESTER INFIRMARY.—Assistant House Physician for six months. Salary at rate of £80 per annum, with board, apartments, and washing.

LINCOLN COUNTY HOSPITAL.—Junior House Surgeon, unmarried, for six months. Salary at rate of £100 per annum, with board, residence, and washing.

LONDON FEVER HOSPITAL, Liverpool-road, N.—Assistant Resident Medical Officer. Salary £150 per annum, with residence and board.

MANCHESTER, ANCOATS HOSPITAL.—Assistant House Surgeon. Salary £70 per annum, with board, residence, &c.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Hampstead and Northwood.—House Physician at Northwood. Salary £75 per annum, with board, residence, and washing.

REDHILL, EARLSWOOD ASYLUM.—Junior Assistant Medical Officer, unmarried. Salary £150 per annum, with board, residence, and washing.

ROYAL NATIONAL ORTHOPÆDIC HOSPITAL.—Resident House Surgeon, unmarried, for six months. Salary £100 per annum, with board, residence, and washing.

ST. MARY'S HOSPITAL, London, W.—Resident Assistant Anæsthetist for six months. Salary at rate of £100 per annum, with board and residence.

SAMARITAN FREE HOSPITAL FOR WOMEN, Marylebone-road, N.W.—Honorary Dentist.

SUNDERLAND, CHILDREN'S HOSPITAL.—Resident Medical Officer for six months. Salary £80 per annum, with board, residence, and laundry.

SUNDERLAND ROYAL INFIRMARY.—House Physician for six months. Salary £80 per annum, with board, residence, and laundry.

TOOTING, S.W., FOUNTAIN ASYLUM.—Second Assistant Medical Officer, unmarried. Salary £180 per annum, with board, lodging, and washing.

WEST LONDON HOSPITAL, Hammersmith-road, W.—Assistant Anæsthetist.

WINCHESTER, ROYAL HAMPSHIRE COUNTY HOSPITAL.—House Physician. Salary £80 per annum.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—House Surgeon for six months. Salary £80 per annum, with board, rooms, and laundry.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of a vacancy as Certifying Surgeon under the Factory and Workshop Act at Youlgreave, in the county of Derby.

Births, Marriages, and Deaths.

BIRTHS.

GLADSTONE.—On Dec. 22nd, at Rosedale, Sydenham-road, S.E., to Dr. and Mrs. Howard Gladstone, a son.

HAYNES.—On Dec. 23rd, at Markfield, near Leicester, the wife of H. G. L. Haynes, M.R.C.S., L.R.C.P., of a son.

HUNT.—On Dec. 19th, at Carlisle Mansions, Westminster, the wife of E. Henderson Hunt, F.R.C.S., of Secunderabad, India, of a daughter.

ORMEROD.—On Dec. 18th, at Beauchamp Lodge, Wimborne, the wife of Ernest W. Ormerod, M.D., of a daughter.

MARRIAGES.

BOLTON—GEORGE.—On Dec. 21st, at St. Marylebone Parish Church, Charles Bolton, M.D., F.R.C.P., to Ethel Mary, elder daughter of the late Mr. Henry George.

CURTIS—MURPHY.—On Dec. 28th, at Ewell, by the Rev. A. L. Watt, George Herbert Curtis, M.R.C.S., L.R.C.P., L.D.S. Eng., third son of Mrs. Curtis, Ewell, to Florence Emily, elder daughter of Mr. and Mrs. Murphy, of Eaton-square, London.

PALMER—CORFE.—On Dec. 19th, at the Church of St. Cross, Winchester, C. J. Linton Palmer, M.R.C.S., L.R.C.P., Stoke House, Gosport, to Henrietta Margaret, daughter of Mr. C. C. Corfe.

SAVAGE—MARRIAGE.—On Dec. 23rd, at Little Waltham Church, Ernest Smallwood Savage, M.A., M.B. Oxon., F.R.C.S., to Constance, daughter of Henry Marriage, of Ayletts, Broomfield, Chelmsford.

SAWYER—THOMAS.—On Dec. 9th, at the Parish Church, Haseley, Warwickshire, R. Fitz-James Sawyer, of the Midland Circuit, younger son of Sir James Sawyer, M.D., F.R.C.P., and Lady Sawyer, of Haseley Hall, and Winifred, daughter of the late Rev. D. Thomas, M.A., Rector of Garsington and Fellow of Trinity College, Oxford.

DEATHS.

HUME.—At 4, Ellison-place, Newcastle-on-Tyne, Frances Diana, wife of George Haliburton Hume, M.D.

SWINDALE.—On Dec. 17th, at Warrington-road, Ipswich, John Popham Swindale, M.R.C.S. Eng., late of Binfield, Berks, aged 69 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE SUPERVISION OF AN INDIAN PILGRIM FAIR.

WE have received a copy of the official report on the Ashadhi Fair held at Pandharpur in Bombay Presidency during last July. 143,000 pilgrims were estimated as visiting Pandharpur during the progress of the fair, which lasts for nine days, and during which time the pilgrims pass in a continuous queue through Vithoba's temple and undertake the ceremony known as *darshan* ("Salute the God"). The fair passed off very successfully, there being an entire absence of epidemic disease, and the number of deaths did not average more than three per diem. Major H. A. F. Knapton, I.M.S., Deputy Sanitary Commissioner of the district, was assisted by a staff of 19 assistant surgeons, and the medical arrangements left nothing to be desired. The cholera hospital had been improved by the provision of wire-gauze netting to the windows to render them fly-proof. A supply of warm blankets and saline-injection apparatus, with an establishment of nurses and ward-boys, were kept ready, but fortunately not a single case of cholera or other epidemic disease occurred during the fair. The following among other sanitary precautions were taken. A large police force was employed; their duties were multifarious, including the guarding of the water-supplies. All the wells in Pandharpur with steps were closed temporarily. On the roads leading to the town water-drawers were put on all the wells to guard against pollution. Trench latrines were placed at a distance from the river and access to the river was protected by barbed wire fences and cactus hedges. A party of sanitary inspectors, nine in all, were employed on patrol duty in the outskirts of the town to prevent people squatting on open spaces. As a result the fields were kept clean. The latrines and portions of the river where washing was prohibited were marked with large flags of different colours. Muslin was provided for all sweetmeat sellers in the town, and they were enjoined to keep their goods covered with it. A Marathi leaflet containing simple directions to the pilgrims was printed, and 30,000 copies were distributed.

A WARNING.

Dr. A. Ogier Ward, 37, Onslow-square, S.W., writes:—A man of medium height, with spotty face and (I think) a moustache, presented a note addressed to me on 2nd inst. in the evening. It purported to be written by himself, and stated that he had been referred to me by a priest at the Brompton Oratory for a letter for a skin hospital. During the time my servant took to bring me the note and for me to read it and go into the hall, the man, who was left standing on the mat, had secreted an umbrella in the leg of his trousers. He went sideways down the front steps bowing and apologising for troubling me. He has visited two other practitioners near. If he calls, any medical man is requested to ring up the nearest police station.

Mr. John Dunlop wishes to make a correction in his letter published in THE LANCET of Dec. 16th, p. 1731. He fears that the words "contract practice on the lines of the National Deposit Friendly Society, however, is not quite in harmony with my ideas of sound and honest practice" may give the impression that he doubts the soundness and honesty of the principles of that society. This is not the case. He has always quoted the society as a model.

S. M. S.—A classified list such as our correspondent inquired for would lend itself to many abuses and could not be of advantage to the public.

A P. & O. Pill Mixer will find that the correction he sends was covered by a letter in our last issue from the author of the book.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced for the next few months:—

Dec. 27th-30th (Baltimore).—American Physiological Society.

In 1912:—

Jan. 20th-27th (Hong-Kong).—Second Biennial Congress of the Far Eastern Association of Tropical Medicine.
Feb. 13th-14th (London).—Central Poor-Law Conference.
March 7th-11th (Berlin).—Thirty-third Balneological Congress.
March 23rd-April 4th (London, Royal Agricultural Hall).—International Smoke Abatement Exhibition.
,, (London).—First Congress of Pure Food and Health Society of Great Britain.
April 1st-7th (Tunis).—Twenty-second Congress of French-speaking Alienists and Neurologists.
,, 14th-20th (Rome).—Seventh International Congress on Tuberculosis.
,, 15th-18th (Wiesbaden).—Twenty-ninth German Congress for Internal Medicine.
,, (Rome).—Seventh International Congress of Dermatology and Syphilology.
,, (Giessen).—Congress on Study of Families, Inheritance, and Race Hygiene.
Spring (London).—Second Optical Convention.
May 7th-17th (Washington).—Ninth International Red Cross Conference.
,, 25th-27th (Paris).—International Musical Festival.
,, 27th-June 1st (London).—Eighteenth International Congress of Americanists.
,, (London).—International Horticultural Exhibition.
June 24th-27th (London).—The (Biennial) Health Conference and Exhibition.
,, (London).—Missionary Exhibition.
,, (Dublin).—Celebration of the Bicentenary of the School of Physic in Ireland (Medical School of Trinity College, Dublin).

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).

THURSDAY.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION, at 11, Chandos-street, W., at 8 P.M.

Specimens:
Dr. Drummond Maxwell: Angio-chorioma of Uterus.
Dr. Inglis Parsons: (1) Fibroid of Uterus Undergoing Degeneration; (2) Fibroid Uterus Removed 20 Years after Apostoli's Treatment.
Dr. Dauber: Suppurating Ovarian Cyst with Sarcomatous Degeneration of its Wall.
Dr. Blair Bell (Liverpool): (1) Exfoliation of Endometrium during Menstruation; (2) Bilateral Solid Tumours of the Ovary, probably Carcinomatous Sarcomata.

Short Communications:
Dr. Colwell and Dr. Glendining: On the Presence of Blood-pigment in the Fæces of the Newborn Child.
Dr. Swayne (Clifton): Two Cases of Missed Labour.
Dr. Blair Bell: Case of Rhabdomyosarcoma of Uterus.

Paper:
Dr. Briggs (Liverpool): On the Relative Size of the Uterus in Cases of Hydatid Mole (with illustrative cases and specimens).

NORTH-EAST LONDON CLINICAL SOCIETY, Prince of Wales's Hospital, Tottenham, N.

THURSDAY.—4.15 P.M., Dr. W. J. Hadley: Diseases of the Colon.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye.
TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin.
WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Simson: Diseases of Women.
THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye.
FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin.
SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

ROYAL INSTITUTION OF GREAT BRITAIN, Albemarle-street, Piccadilly, W.

TUESDAY.—3 P.M., Dr. P. C. Mitchell: The Childhood of Animals—III., Colours and Patterns of Young Animals.
THURSDAY.—3 P.M., Dr. P. C. Mitchell: The Childhood of Animals—IV., Young Animals at Home.
SATURDAY.—3 P.M., Dr. P. C. Mitchell: The Childhood of Animals—V., The Feeding of Young Animals.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (1st).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), Central London Throat and Ear (Minor 9 A.M., Major 2 P.M.).

TUESDAY (2nd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London, (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.) Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.), Royal National Orthopædic (9.30 A.M. and 4 P.M.).

WEDNESDAY (3rd).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's 2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

THURSDAY (4th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal National Orthopædic (9 A.M. and 3.30 P.M.), Royal Ear (2 P.M.), Children Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

FRIDAY (5th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M., Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Royal National Orthopædic (3.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.)., Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

SATURDAY (6th).—Royal Free (9A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.), Hospital operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

The Index and Title-page for the current half year are published in this issue, which completes the second volume of the year 1911.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1911 will be ready shortly. Bound in cloth, gilt lettered, price 16*s.*, carriage extra.

Cases for binding the half-year's numbers are now ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

A

Abattoir, export, of Copenhagen and import abattoir of Manchester, 1433
Abattoirs, failure of reform of, at Liverpool, 1517; municipal, at Newcastle-on-Tyne, defective, 1367; public, demand for, 1367, 1433, 1517; proposed, for Weston-super-Mare, 970
Abbe, Prof. C., award of Symons gold medal to, 1519
Abbey Sanatorium, 408
Abdomen, Acute, Clinical Lectures on, 1911 (Mr. W. H. Battle) (review), 961; fat, operation for, 562; Proper, Described and Illustrated by Text and Plates (Dr. W. C. Morton) (review), 1141
Abdominal conditions, two unusual, in children, 685; operations in women, mortality not improving, 1061; abdominal and pelvic surgery, year's work in (Prof. R. Morison), 1683; surgery, indications for employment of spinal anæsthesia in, 511
Abdominal wall, suture of, without buried sutures, 1660
Aberchirder Cottage Hospital, 197
Abercrombie, Dr. R. G., cases illustrating methods of mechanical treatment, 1338
Aberdeen, doctors of, and Family Medical Fund, 1742; effect of inclusive fee in, 1521; epidemics in, 1804; increase of tuberculosis in, 550; medical men of, and contract medical practice, 1521; and National Insurance, 54; population of, 54; post-graduate medical study at, 660; protests of medical profession in, with regard to National Insurance Bill, 1582; scarlet fever in, 1521
Aberdeen City Hospital, extensions at, 183
Aberdeen county committee, appointment of school medical officers, 477
Aberdeen county school medical inspection staff, 1436
Aberdeen Dispensary, donation to, 858
Aberdeen Dispensary and Maternity Hospital, annual meeting, 1803
Aberdeen Infirmary, water charges to, 858
Aberdeen parish council, medical officers, attendance of, at confinements, 191
Aberdeen provincial committee, new medical officer, 477
Aberdeen Royal Infirmary, information for students, 613
Aberdeen, University of, 260; Anthropological Society, 54, 55; appointment of lecturer in bio-chemistry, 1165; diploma in State medicine, 642; new lectureship for, 1662; pass lists, 267; rectorship of, 191; regulations for medical examination, 613; revised regulation for Carnegie fees at, 1165
Abergele, proposed sanatorium for (Parliamentary question), 1451
Abnormalities, two rare, observed in course of operations (Mr. J. D Malcolm), 1401, 1589
Abortifacient, use of diachylon as, 1531
Abortion, early, case of first pregnancy ending in, 1271; followed by abscess for ten years, 925
Abraham, Dr. J. J., one bell, 1802; "The Surgeon's Log," 1718
Abrahams, Dr. A., chloretone in sea-sickness, 188
Abrams, Dr. A., Diagnostic Therapeutics: Guide for Practitioners in Diagnosis by Aid of Drugs and Methods other than Drug-giving, 1910 (review), 299
Abscess for ten years following abortion, 925
Abscess formation, fate of appendix after, 1705
Abscission in treatment of metastatic suppurative cyclitis occurring in woman with pyæmia, recovery (Sir W. Collins), 1475
Absinthe, struggle against, 1373
Academy of Medicine, Toronto, 1593
Accessory sinuses, nasal chronic empyema of, four cases illustrating surgical treatment of, 1698
Accidents, two hundred bogus claims for, 1734
Accidents which have occurred through colour-blindness (Dr. F. W. Edridge-Green), 879 (see also Employment, Accident)
Acetanilide poisoning, chronic, 777
Acetone in inoperable cancer of uterus, 1784
Acetonuria in childhood, prevalence and cause of, in medical wards of children's hospital (Mr. R. S. Frew), 1264
Achalme, M. Pierre, and Phisalix, Dr. Marie, the preservation of vaccine virus in hot countries, 1027
Achondroplasia, case of, 1700
Achondroplasia, skeleton of male subject of, 444
Acidity in milk, development of, relation of, to time and temperature, 1408
Acidosis, remarks on (Dr. E. Mellanby), 8, 10; in diabetes mellitus, 1185
Acromegaly caused by fright, 1304
Acoustics, Leitfaden der Akustik für Ohrenärtze, 1911 (Dr. M. Th. Edelmann) (review), 1562
Actinomycosis in Norway, 1152
Adalia, plague in, 787
Adalin, 232
Adams, Mr. P. E. H., case of double proptosis, 1201
Adamson, Dr. H. G., case of sporotrichosis, 510
Addenbrooke's Hospital, information for students, 567
Addison, Mr. O. L., two cases of genu valgum and hyperextension of knee, 1335
Adelaide Medical and Surgical Hospitals, Dublin, information for students, 624
Adenoids and tonsils, removal of, 1284
Adenoma, adrenal, of liver, 1407; cirrhosis and carcinoma of liver, case of, 523
Adler, Dr. A., and others, Ueber den Selbstmord insbesondere den Schüler-Selbstmord (Suicide, especially of School-children), (review), 766
Adnexa, the, affections of, relation of appendix to causation and surgical treatment of (Dr. H. Macnaughton-Jones), 295; uterine and appendix cæci, pathological relationship between (Mr. J. Birt and Mr. T. C. English), 498
Adrenal glands, influence on primary and secondary sex characters, 1555
Adult, case of acute poliomyelitis in (Dr. C. M. H. Howell and Dr. B. T. Parsons-Smith), 812; intussusception of vermiform appendix in, case with pathological report and explanation (Dr. J. H. Watson), 942; late or retrograde infantilism of, 1417
Adulteration of food products in Austria, 1373
Advertising of patent medicines, 48
Advisory Committee to the Insurance Commissioner (Parliamentary question), 1450
Aeroplane flying, physiological effects of, 409
Æsculape (review), 953
After-care association for persons discharged from asylums for insane, appeal for funds, 1747
Affleck, Dr. J. O., knighthood bestowed upon, 329

AFRICA, SOUTH, CORRESPONDENCE FROM.—The Census in South Africa; Medical Council muddle, 58—Health administration in, 106—Native nurses in, 796—South African memorial to King Edward; New order of nurses, 129—Prevalence of tuberculosis, 130—Medical profession and the Union Government; Medical School of South Africa; Prevalence of small-pox, 481—Leprosy in Basutoland; Proposed Johannesburg research laboratory, 482—Retirement of Government health officers; Discontent in the profession; Transmission of leprosy, 800—South African scurvy; Illicit liquor trading; Transfer of a well-known official, 801—New Union health organisation; Census returns; Johannesburg Hospital, 974, 975—Libel action against Gen. Hertzog; Monthly meeting of Chamber of Mines, 1305—Farewell dinner to a practitioner; Need for public slaughter-houses in South Africa, 1306—Medical prospects in South Africa, 1438—Medical legislation; Cape Province Medical Council, friction in the Johannesburg Hospital; Pneumonia investigation, Rietfontein Lazaretto, 1745; Curious Government Commission, 1807

Africa, South, Travel in, Off the Main Track (Mr. L. P. Hyott) (review), 1276
Africa, West Coast of, yellow fever on, 459
After-care Association, 1441
After-care of consumptive patients (Dr. H. W. McConnel), 431
Agglutinating power of the blood, its relation to intestinal hæmorrhage in typhoid fever (Dr. H. Whitehead), 1067
Agra and Oudh, United Provinces of, sanitary administration of, 1576
Air-passages, upper, part played by, as avenues of general infection, 157
Airway, oral, in anæsthesia, 1335
Aitken, Mr. D. M., discussion on division of posterior spinal nerve roots for pain, visceral crises, and spasm, 95
Albania, cholera among troops returning from, 854
Albu, Prof. A., Beiträge zur Diagnostik der inneren und chirurgischen Pankreaserkrankungen (Contributions towards the Diagnosis of Medical and Surgical Diseases of the Pancreas), 1911 (review), 504
Albumin reaction in tuberculous sputum, 1084, 1485, 1802; value of, 1660
Albuminuria (Les Maladies de la Cinquantaine, tome iv. (Dr. A. Leclercq) (review), 1018; simulation of, 1167
Alcock, Mr. F. H., linimentum ammoniæ, 320
Alcohol as a drug, 1704
Alcohol, consumption of, in 1910, 1663; influence of, on body temperature and on heart, 1497; and insanity, 308; and opium in Wei-Hai-Wei, 343; consumption in France, 1047
Alcoholic extract of guinea-pig's heart, 1411
Alcoholism, chronic, and syphilis, 1394; and Drug Narcotism, Modern Treatment of (Dr. C. A. McBride) (review), 688; and inebriety (leading article), 772; parental influence of, on offspring, 536
Alderton, Mr. T. G., immediate and ultimate results after gastro-enterostomy for gastric and duodenal ulcer, 96
Alexander, Dr. D. A., portal pyæmia and hæmorrhoids, 884
Alexander, Dr. D. M., researches in epilepsy, 1072
Alexander, Dr. F. W., poliomyelitis and public bathing, 1646
Alexander, Dr. W., the surgical treatment of some forms of epilepsy, 932
Alexander of Trales, newly discovered manuscript of, 558
Alfred Hospital, Australia, 482
Alienists and Neurologists of, French-speaking Countries' Congress of, 728
Alimentary Canal; Sensibility of, Goulstonian Lectures on (Dr. A. F. Hertz) (review), 767
Alimentary tract, treatment of certain diseases of, combined with internal administration of metallic silver, 512
Alkaline solutions, intravenous injections, dangers of, 960
Allanson, Dr. H. E., and Moore, Dr. F. C., influence of certain accessory food stuffs on gastric secretions, 1551
Allbutt, Sir T. C., and others, value of sanatorium treatment, 180
Allen, Mr. H. E., death of, 174
Allen and Hanburys, Messrs., revised price list of, 202
Allison, Dr. T. M., National Insurance Bill, 251
"Allopathy," abolition of, mysterious reform, 1381
Allport, Mr. W., discussion on operative treatment of glaucoma, 382
Ally compounds, physiology of, 509
Altitudes, high, treatment of phthisis at, 1122
Altmann's granules, absence of, in diagnosis of malignant disease, 1213
Alvarenga prize of the College of Physicians of Philadelphia, 1402
Amateur Gardeners' Diary and Dictionary for 1912 (review), 1830
Ambulance arrangements at the Coronation (Parliamentary question), 736
Ambulance work, Coronation medals for, 339
Ambulance work in India, 1525
"Amende," an, 339
America, infant mortality in, urgent call for action, 1148; summer health propaganda in, 394; South, conditions of practice in, 1158; foreign medical practice in, 1438
American Electro-therapeutic Association, annual meeting, 1169
American Hospital Association, annual conference, proceedings, 1047; meeting of, 1169
American Journal of Gastro-enterology (review), 231
American Proctological Society, thirteenth annual meeting, 781
American lifts, do they shorten life? 1524
"Ammochlorique" inhaler, 1311
Anæmia, Egyptian, blood changes in bilharziasis, with special reference to (Prof. H. B. Day), 1328; malignant, hæmolytic type, 1479; prevalence of, among wireless telegraphy operators, 1166; splenic, 1408; troph-neurotic, sequel to case (Dr. T. W. Parry), 17; and want of ventilation in French navy, 703
Anæsthesia, acute bronchitis and (?) pleurisy following, 1335; by ether inhalation, pioneer of, 1701; dental, electrical osmosis for, 1343; induction of, for extraction of teeth, persistent vomiting during, 1335; local, omnopon a potent adjuvant to, 672; oral airway in, 1335; plus pressure, for exploratory thoracotomy, case of (Mr. F. H. Wallace), 220; report of three deaths under, 1335; spinal, indications for employment of, in abdominal surgery, 511; spinal, in prostatectomy, 1556
Anæsthetic (see Skin anæsthetic)
Anæsthetics, expenses allowed for, at Bridgwater Workhouse Infirmary, 970; in intestinal obstruction, 969; value of gastric lavage, 123; legislation with regard to, 109, 189; position of present reform movement in, 47, 251, 325; progress in (leading article), 835
Analysis, Volumetric, New Reduction Methods in (Dr. E. Knecht and Miss E. Hibbert) (review), 1491

ANALYTICAL RECORDS FROM THE LANCET LABORATORY.—Adalin, 232—(1) Alcoholic Extract of Guinea-pig's Heart; (2) Hæmolytic Serum for Sheeps' Corpuscles; and (3) Epinine for ophthalmic use, 1411—Aponal, 1412—Ceregen Food, 691—Cholegestin, 1492—Dental Preparations, 692—(1) Epinine and Cocaine Hydrochloride; and (2) Tabloid Xaxa and Caffeine, 231—Extra Stout, 1144—Fireproof Cloth, 692—Formitrol, 1412—(1) Golden Shred Orange Marmalade; and (2) Silver Shred Lemon Marmalade, 232—Halakones, 691—"Health and Strength" Cocoa, 1492—(1) Hegonon; (2) Arthigon; (3) Atophan; and (4) Hormonal, 1143—Home-made Marmalade, 692—Jameson's Irish Whisky, 691—Kacepe Balsam, 1143—Liqueur Advocaat, 231—(1) Malt Extract; and (2) Malt Extract with Cod-liver Oil, 1143—Malt Extract with Iron Iodide, 691—Marvis Flakes, 1411—Me-malto Wine, 692—Mergentheim Tablets, 1143—(1) Milk-food; and (2) Health Diet, 692—Oriental Tooth-paste, 1411 Pepto-Mangan (Gude), 1411—"Topmast" Sardines, 231—Vin de Graves, 692—Vittel Water (Grande Source), 1411—X-ray Proof Cloth, 231

Anaphylaxis (see also Hypersensitiveness)
Anastomosis, sapheno-femoral varicose veins, and, 1350
Anatomical Institute, Vienna, disorderly scenes at, 1238
Anatomist, Catholic, Thoughts of (Prof. T. Dwight) (review), 1632
Anatomy, Microscopical, and Histology, Instruction in (Prof. R. Krause) (review), 893; Morbid, and Pathology, Manual of (Dr. T. H. Green) (review), 364; of Brain and Spinal Cord (Dr. J. R. Whitaker) (review), 892; principles of (Dr. Cuthbert Morton), 1298; Abdomen Proper Described and Illustrated by Texts and Plates (Dr. W. C. Morton) (review), 1141; scope of, 1095; Sectional and Typographical, Clinical Atlas of (Prof. R. J. A. Berry) (review), 686
Anatomy in Scotland during life and times of Sir John Struthers, 1521
Ancoats Healthy Homes Society, report of, 1045
Ancoats Hospital, work and deficit, 1369
Anderson, Mr. A. R., removal of calculi from sac of posterior wall of bladder, 1557
Anderson, Prof., on variation, with special reference to muscle, 444
Anderson, Mrs. Garrett, remarks at annua meeting of Research Defence Society, 32
Anderson, Dr. J. F., and Goldberger, Dr. J., experimental measles in the monkey, 699, 1318
Anderson, Mr. W. D., pruritus ani, 1232
Anderson's College Medical School, Glasgow, information for students, 609
Andrew, Dr. J., obituary, 971
Andrew, Mr. J. G., discussion on treatment of general septic peritonitis, 373
Aneurysm, double, of thoracic aorta, case of, 1554; of first part of aorta, 1554; popliteal, case of, 1554
Aneurysm, abdominal, two cases treated by operation, 507
Aneurysm of third part of arch of aorta, 1705
Aneurysms, intrathoracic (Dr. G. Steell), 1605
Angiomata, nervous influence in causation of, 445
Angina sine dolore and gastric deflation, case of, 362
Animal Micrology, Practical Exercises in Microscopical Methods (Dr. M. F. Guyer) (review), 503
Animals, living, experiments on (Parliamentary question), 341, 416, 556; stray, wholesale destruction of, in New York, 1102; viability of human carcinoma in, 1160; (Dr. C. L. Williams), 938; and men, action of tropical sun on, 777
Ankylostomiasis and bilharziosis in Egypt (Capt. G. W. G. Hughes), 880
Annali di Medicina Navale e Coloniale (review), 101
Annals of Tropical Medicine and Parasitology (review), 1276, 1711
Annett, Dr. H. E., sclerostomiasis in equines, 401

ANNUS MEDICUS.

Medicine.—**Tuberculosis**; **Measles**; **Diphtheria**; **Acute poliomyelitis**; **Plague**; **Anthrax**; **Ankylostoma infection**; **Rheumatoid arthritis**; **Polycythæmia and plethora**; **Diseases of the heart**; **Diseases of the lungs**; **Diseases of the nervous system**; **Lectures of the year**, 1833

Surgery.—**The vermiform appendix**; **Intussusception of the vermiform appendix**; **Foreign bodies in the stomach**; **Rupture of abdominal viscera**; **Rupture of the large intestine from compressed air**; **Complete gastrectomy**; **Pancreatic cyst**; **Intestinal obstruction**; **The functions of the omentum**; **Excision of bowel for tuberculosis**; **Evagination of Meckel's diverticulum**; **Iodine in the preparation of the skin for operation**; **Section of the posterior roots of the spinal nerves**; **Cleft palate**; **Quinine for the prevention of pain after amputation**; **Operation for stone in male bladder**; **Transperitoneal cystotomy**; **Torsion of the testis**; **Ureteral grafts**; **Direct gastroscopy**; **Myositis ossific ns traumatica**; **The treatment of syphilis**; **Lymph-angioplasty**, 1837

Obstetrics and Gynæcology.—**The follicle cells in the ovary**; **The uterine mucosa in menstruation and pregnancy**; **the action of the chorionic cells and the function of the decidua**; **The theory of enzygotic (monochorionic) twins**; **The nature of hæmatocolpos fluid**; **The modern treatment of contracted pelves**; **Operative treatment of cancer of the cervix uteri**; **The dangers of fibroid tumours**; **The suprapubic transverse fascial incision in gynæcology**; **The present position of vaginal operations in relation to the uterus and its adnexæ**, 1841

Ophthalmology.—**Publications**; **Cataract**; **Glaucoma**; **The treatment of lacrymal obstruction**; **Salvarsan ("606") in eye disease**; **Serum and Serum therapy**, 1844

Dental Surgery.—**Dental disease in children**; **Dental caries**; **Periodontal disease**; **Irregularities of the teeth**; **The histology of the teeth**; **Prosthetic dentistry**; **Miscellanea**; **Obituary**; **New publications**, 1845

Anæsthetics.—**Intratracheal ether insufflation**; **Intravascular anæsthetisation**; **Rectal ether narcosis**; **Nitrous-oxide gas in major operations**; **Scopolamine and morphine**; **Omnopon**; **Spinal analgesia**; **Local analgesia**; **Post-anæsthetic complications**; **Treatment of respiratory failure during anæsthetics**; **Effects produced by ether**; **Effects produced by chloroform**; **the Anæsthetics Bill**, 1847

Public Health.—**Plague and cholera**; **Measles and whooping-cough**; **Scarlet fever**; **Small-pox**; **Enteric fever and diarrhœa**; **some effects of the hot and dry summer**; **Epidemic poliomyelitis**; **Tuberculosis**; **final report of the Royal Commission**; **Compulsory notification of pulmonary tuberculosis**; **Industrial**

hygiene: effect of humidity on health; Industrial cancer and lead poisoning; Medical inspection of school children; Milk and food-supply; The census: Registrar-General's reports; Sanitary legislation; Conferences and exhibitions; The Coronation celebrations, 1852
Tropical and Exotic Diseases.—Bureaux and bulletins; Commissions and investigations; The incidence of exotic disease; Cholera in Europe; Cholera in North Africa; Cholera in the Near East; Cholera in India and the Far East; Cholera in America; Plague in Asia and Oceania; Plague in America; Plague in Europe; Plague in Africa; Plague in the Near East; Yellow fever in South America and the West Indies; Yellow fever in West Africa and elsewhere; The alleged specific organism of yellow fever; The Paris International Sanitary Conference of 1911, on Cholera, Plague, and Yellow Fever; Small-pox on the continent of Europe; Small-pox in Africa and the Near East; Small-pox in Asia and Oceania; Small pox in America, 1855
Forensic Medicine.—Acts of Parliament; Regulations as to the Sale of Poisons; Workmen's Compensation Act, 1906; Cases in the House of Lords; in the Court of Appeal; in the Divisional Court; in the High Court; in the county courts; in the police courts; in the coroners' courts, 1861
Anatomy—Anatomy of the head and neck; the abdomen; Anatomy of the chest, and other regions; Embryology and anthropology; Obituary, 1864

The Housing Problem in South Wales, 1878
Obituary, 1878
National Insurance, 1880

Anopheles (see Mosquitoes)
Anophelines (see Mosquitoes, anopheline)
Anthracosis, pulmonary, origin of, 521
Anthrax, death from, in laboratory 273, 343; fatal case in Liverpool, 1741; incidence of (leading article), 530; infection due to imported hides and skins, prevention of, by the Seymour-Jones formic-mercury process (Dr. C. W. Ponder), 1260; Parliamentary question, 1815; prevention of (Parliamentary question), 488; at Bedford, 101
Anthropology, recent work in, in Egypt and Nubia, 1569
Antivivisection shops, effect of, on Research Defence Society, 1307
Antipyrine rash, case exhibited, 1336
Antisepsis and asepsis, 547
Antistreptococcus serum, case of acute plastic iritis markedly benefited with (Mr. A. A. Bradburne), 883
Antisyphilitic treatment, comparative value of various methods estimated by Wassermann reaction (Mr. H. W. Bayly), 1332
Antisyphilitics, experimental comparison between "606," mercury, and iodide of potassium, as (Dr. J. McIntosh and P. Fildes), 940
Antituberculosis schools, 315
Antituberculosis Society, free advertising for, 554
Antityphoid examination in United States, 1524
Antityphoid vaccination, compulsory, in United States Army, 1102
Antivaccinationists, attitude of, in Montreal, 554; increase of, 155
Antral cases, two, 453
Antrim, County, Infirmary, 1237
Antrim Infirmary, resolution as to National Insurance Bill adopted at monthly meeting, 56
Antrum, chronic suppuration of, 1179; maxillary, acute inflammation of, 1179
Antrum of Highmore, acute inflammation of, with eye complications, 1075; gumma of, 1483
Anus, imperforate, in association with sacro-coccygeal meningocele, 1555
Aorta, aneurysm of third part of arch of, 1705; disease of, with patent arterial duct, 156; thoracic, double aneurysm of, 1554
Aortic arch, acute vegetative endarteritis of, 1483
"Aoutas" or harvest bugs, pest of, in France, 922
Apes and man, foramina of fibulæ in, 509
Aphasia, transient, and paralysis in states of high blood pressure and arterio-sclerosis, 1349; and hemiplegia of embolic origin, 1485
Aponal, 1412
Apothecaries' Hall of Ireland, 551; regulations for examination, 624; report as to final examinations discussed at General Medical Council, 1637; appointment of examiners for 1912, 1824
Appendicitis caused by metal dish-cloths, 927; chronic dilatation of colon as test for, 902; experimental production of, by intravenous inoculation of diplococcus (Dr. F. J. Poynton and Dr. A. Paine), 1189, 1211; fulminating, presence of liver dulness in, ligature-temperature (Dr. F. W. Forbes-Ross and Dr. J. Chalmers), 683; several attacks in appendix in sac of scrotal hernia (Lieut. Col. C. H. James), 1771; treatment of, surgical, advances in, 288; without physical signs, 507
Appendicostomy, case of ulcerative colitis shown after, 1337
Appendix, cæci and uterine adnexa, pathological relationship between (Mr. J. Birt and Mr. T. C. English), 498; fate of, after abscess formation, 1705; Life-history, Function, and Inflammation of (Mr. E. M. Corner) (review), 1142; relation to causation and surgical treatment of affections of the adnexa (Dr. H. Macnaughton-Jones), 295; vermiform, foreign bodies in (Mr. L. A. Bidwell), 944; and their Complications, Surgery of Diseases of (Mr. W. H. Battle and Mr. E. M. Corner) (review), 363; inflamed, cæcum and ileo-cæcal valve contained in sac of strangulated left inguinal hernia, 1198; intussusception in adult, case with pathological report, and explanation (Dr. J. H. Watson), 942
Appointments, weekly list of, 63, 136, 199, 271, 342, 417, 488, 557, 738, 803, 865, 926, 982, 1049, 1111, 1173, 1242, 1309, 1380, 1451, 1529, 1600, 1672, 1750, 1817
Arabs and Kurds, medical and surgical methods of, 1095
Archibald, Surg. W. F., R.N., death of, 41
Archives of the Roentgen Ray (review), 1410
Archivos Brasileiros de Medicina (review), 1080
Ardagh, Bishop of, and election of medical officers, 1663
Armfield, Mr. J. M., veterinary training and the public health service, 1590
Armstrong, Dr. G. E., appointment of, 480; Presidential address at the meeting of Canadian Medical Association in Montreal, 125
Armstrong, Mr. W., treatment by radium water, 447
Army, British, head-dress of, 1040; health of, in 1910, 1511 (1910), 1787; tuberculosis in (Parliamentary question), 270, 1528; vaccination in, 794, (Parliamentary question), 1379; French, disease and mortality in, 56; dogs in medical, service of, 409; Prussian, medical stores in, 1228; Indian, smoking in, 1667
Army of United States, compulsory vaccination in, 1102
Army and Navy Male Nurses' Cooperation, 1077, 1175
Army Medical Service, regulations, 630; (see also Services, naval and military medical)
Arnaud, Mr. F. W. F., composition of diabetic foods, 319
Arran, Earl of, Children's Country Holidays Fund, 805
Arrhythmias, the (Les Arythmies) (Prof. H. Vaquez) (review), 300
Arsenic poisoning at Lamlash, 858
Arsenical compounds in treatment of syphilis, 1385; arsenical poisoning among viticulturists, 192
Arterial degeneration in women, 205
Arterial lesions in ancient man and their lessons, 534
Arteries, physical strain of, management, 209; surgical affections of (M. P. Delbet and M. P. Mocquot) (review), 1204
Arterio-sclerosis and high blood pressure, transient aphasia and paralyses in, 1349; and syphilis, 1394; Les Maladies de la Cinquantaine, tome i. (Dr. A. Leclercq) (review), 1018
Artery (spermatic), ligature of, in operation for varicocele, 1026, 1094
Arteriomyomatosis, 1552
Arthigon, 1143
Arthritis, blennorrhagic, 1437; diseases, chronic, nomenclature, 1775; gonococcal vaccine treatment of, 1272
Arthritis deformans, treatment of, 242
Ascites, absence of, in tuberculous peritonitis which was apparently cured by incision, 918; and spleno-portal thrombosis in case of toxic cirrhosis, 1478; associated with cirrhosis of the liver, case of, 1479; chylous, accompanying case of myeloid leukæmia (Dr. H. S. Furness and Dr. G. F. Stebbing), 889; due to cirrhosis hepatis, case of, 1479
Asepsis and antisepsis, 547
Ashanti, health and sanitation in, 739
Ashby, Dr. H. T., headache in children, 1406
Ashforth, Mr. T. L., National Insurance Bill, 1160
Asia Minor, lack of medical men in, 412; and Mesopotamia, cholera in, 854
Askin, Dr. T. C., the National Insurance Bill, 1361, 1784
Asklepios and Hygieia, new Greek monument to, 1243
Asphyxia neonatorum, pathology, 379; treatment, 379
Aspirin and salicylates, some effects of, 780; toxic, effect of, 761, 916, 970, 1094
Assam and Eastern Bengal, sanitary report of, 924
Association of Certifying Factory Surgeons (Incorporated), annual dinner, 1705
Association of Infant Consultations and Schools for Mothers, 340
Association International d'Urologie, Congress of, 485
Association of Medical Officers of Health, council meeting, 132
Association of School Medical Officers for Scotland, 1301, 1591; general meeting, 35
Asthma, bronchial, fæcal accumulation as cause of, 1304; its Nature and Treatment (Das Asthma, sein Wesen und seine Behandlung) (Dr. Brugelmann) (review), 365; treatment of, discussion on, 367, 368; varieties of discussion on 367, 368
Astor, Mr. W. W., M.P., the economic cost to the community of tuberculosis, 315
Asylum, discharged patients of, assistance for, 1167
Asylum accommodation in South African Union, need for, 975
Asylum for the counties of Salop and Montgomery and for the borough of Wenlock (report for the year 1910), 1507
Asylum Officers Bill, 1028
Asylum Officers (Superannuation) Bill, 134; (Parliamentary question), 1379
Asylum reports, 962
Asylums, old people in, 1237
Asylums, proposed construction in Lancashire and Derbyshire, 1376
Ataxy, Friedreich's, case of, 827
Athens, prevention of malaria in, how accomplished, 959
Atkins, Mr. T. W., fees to ship surgeons, 1517
Atophan, 1143
Atthill, Dr. L., Recollections of an Irish Doctor, 1911 (review), 22
Attlee, Dr. W., note on a case of torsion of the testicle, 761
Auber, Dr., wireless telegraphy and anæmia, 1166
Auden, Dr. G. A., medical certificates to justify absence from school, 514
Aufrecht, Prof., tuberculous pleurisy due to embolism, 902
"Aurora," health caravan, 1311
Austen, Mr. E. E., Handbook of the Tsetse Flies (Genus Glossina), 1911 (review), 639

AUSTRALIA, CORRESPONDENCE FROM.—Administrative control of consumption; Imperial University Congress; New South Wales country hospitals, 130 Royal Prince Alfred Hospital, Sydney; Use of hospital funds; Care of children, 130, 131—Control of charities; Alfred Hospital, 482—Friendly Societies Hospital; Medical unionism; morning "nips," 483—Hospitals Bill for New South Wales; Curio's double tragedy; Public Health Department in Victoria; Federal quarantine; British Medical Association; Health of Melbourne; Coronation honour; Prevalence of syphilis, 863—Curious fatality; State sanatoriums; Health of South Australia; Prevalence of syphilis Ninth Australasian Medical Congress;

Cancer cure; Federal quarantine, 1103—Ninth Australasian Medical Congress, 1440—Friendly Societies dispute; Medical service of the Federal defence scheme, 1441—Charge against a medical man; Tenth Australasian Congress; Charities Bill; Pure milk; Melbourne Hospital; Lunacy in Victoria, 1667

Edinburgh School of Medicine for Women, 1164; information for students, 607
Edinburgh University Courts, 1520
Edinburgh and Leith Practitioners' Association, annual dinner, 1301 (see also British Medical Association, Edinburgh branch)
Edmond, Mr. W., notes on a case of operation for ruptured meningo-encephalocele, 1198
Edmunds, Dr. C. W., and Hale, Dr. W., physiological standardisation of ergot, 1419
Edmunds, Mr. W., sanatorium treatment for children, 1735
Edridge-Green, Dr. F. W., accidents which have occurred through colour blindness, 879; discrimination of colour, 497; discussion on method of mapping out blind spot of retina, 519; Hunterian Lectures on Colour-vision and Colour-blindness, delivered before the Royal College of Surgeons of England, 1911 (review), 1080; tetra-chromatic vision, 509
Education, medical, 277; in Denmark, 114; in Germany (Prof. F. von Müller), 1350, 1351; final examination and after, 1353; qualifications of professors, 1354; state subsidies to, 1352; in Norway, 36; in Sweden, 244, 245; veterinary, in relation to public health, 400; and Infant Feeding (Dr. H. Young) (review), 1633
Education medical officer of London County Council, annual report of, 1222
Education of pharmacists from point of view of teacher, 462
Edward Jenner lecture on school health (abstract), delivered at the Medical School of St. George's Hospital (University of London) (Mr. F. E. Fremantle), 347
Edward VII., King, Gloucestershire memorial to, 970; South African memorial to, 129
Egan, Dr. J. A., tuberculin test in cattle, 839
Egypt, bilharziasis and ankylostomiasis in (Capt. G. W. G. Hughes), 880; bubonic plague in, in 1911, 124; foreign medical practice in, 656; need of proper sanitary administration in, 242; pellagra in prisons of, 916; spinal anæsthesia in (Dr. H. E. S. Stiven), 1135; treatment of leprosy in, 467
Egypt and Nubia, recent anthropological work in, 1569
Egypt and the Soudan in 1910, report on, 539
Ehrlich, Dr. P., Aus Theorie und Praxis der Chemotherapie, 1911 (review), 1491; therapeutic action of salvarsan, 1303
Ehrlich Hata ("606"), permanence of cure of, by (Dr. J. McIntosh and Dr. P. Fildes), 213
Ehrlich-Hata remedy ("606"), case of early general paralysis of insane treated by, with fatal result, 1556; mercury and iodide of potassium compared experimentally as antisyphilitics (Dr. J. McIntosh and Dr. P. Fildes), 940
Eichhorst, Prof., treatment of cardiac disease, 1100
Elbow-joint, injuries to (Mr. R. L. Joynt), 817
Elder, Dr. J. M., discussion on wound treatment, 442
Electric current, unusual resistance to, 863
Electrical standardising, testing, and training institute, information for students, 651
Electricity conveyance of, through solids, liquids, and gases, 373 (see also Osmosis, electrical)
Electro-chemical (ionic) treatment of certain gynæcological affections (Dr. S. Sloan), 1759
Electro-therapeutics, apparatus, latest appliances, 344
Electro therapy, causes of failure and success in (Dr. S. Sloan), 15
Elephantiasis, tuberculous, of vulva, 517
Elkington, Deputy-Surg.-Gen. A. G., death of, 41
Elliot, Maj. R. H., discussion on concomitant squint and heterophoria, 454; on extraction of lens in its capsule, 520; observations on trephining the sclera, 381, 382
Elliot-Blake, Mr. H., university and college reform, 1738
Ellis, Mr. H. H., question in eugenics, 796; dreams, 1644
Ellis, Mr. T. S., discussion on wound treatment, 442
Elmslie, Mr. R. C., case of general thyroid malignancy, 1137
Elocution for Ordination Candidates (Rev. C. Gib) (review), 768
Embolism cause of tuberculous pleurisy, 902
Embryology, Laboratory Textbook of, second edition, 1911 (Prof. C. S. Minot), 1015
Embryos of trichina spiralis in blood of trichinosis, 1214
Emery, Dr. W. d'Este, discussion on chorion epithelioma, 523; on comparative value of microscopical methods of demonstrating spirochæta pallida, 523; on pathogenic action of bacillus coli, 456; hypersensitiveness in its various manifestations, especially in relation to serum, vaccines, and tuberculin, 383; salvarsan ("606") and mercury in the treatment of syphilis, 474
Emigration, decreasing, in Ireland, 809; from Ireland, 1099
Emoluments in Indian Medical Service, 124, 171, 917
Emotional dispositions, experimental investigations of, 52
Emotional stress, effects on cardio-vascular system, 205
Emphysema, acute interstitial, 507
Employment accident, sun-stroke as, 1045
Empress Marie Féodorovna Fund, 1669
Empyema, chronic, of nasal accessory sinuses, two unusual complications of, 1403; four cases illustrating surgical treatment of, 1698; healed, double, case of, 1699; rupture of, into œsophagus, 1075; of frontal sinus, followed by abscess of left lobe of brain, 1336
Emrys-Jones, Dr. A., reappointment of, 1422
Encephalitis, acute, case of, 1137
Encyclopædia Britannica, articles on medicine in, 1035, 1355, 1504
Endarteritis, acute vegetative, of aortic arch, 1483
Endocarditis, acute, caused by micro-organism hitherto undescribed (Dr. A. T. Naukiveli), 1134; infective, 1554
Endolytic tubes for clinical diagnosis, 983
Endothelioma of cheek, 1407
Energy and elemental instability (leading article), 695; in Relation to Living Matter (Chaleur Animale et Bioénergetique, 1911, (Dr. J. Lefèvre) (review), 228
Enfield Medico-Ethical Society, Central Midwives Board, and Privy Council, 1215

Engelmann, Dr. W., present position of radium emanation-therapy in Germany, 426
England, clinical teaching in, compared with that in Germany, 1353; exportation of Chinese pork to, 1349; Middlesex Hospital, first lying-in hospital in, 993; position of hydrotherapy in, 74; Recent Progress of (Mr. T. A. Welton) (review), 1139; west, spotted fever in, 549, 725
England and Wales, numbers of insane in, 783
English, Mr. T. C., and Birt, Mr. J., pathological relationship between the appendix cæci and the uterine adnexia, 498
English visitors, advantages of winter term for post-graduate study at Vienna by, 1374
Englishwoman's Year Book, 1912 (review), 1850
Enniskillen, parsimonious board of guardians of, 1437
"Enseignement Medico-Mutuel International," 394
Enteric Fever in the Tropics (Mr. B. N. Ghosh) (review), 1205
Entomology, Second International Congress of, 1571
Enuresis, nocturnal, treated with thyroid gland, 1479; and thyroid extract (Dr. A. C. D. Firth), 1619
Environment, influence of, 2; perception of movement of, 52; or heredity in crime, pauperism, and disease (Justice for the Jukes), 1023
Enzygotic, mono chorionic, twins, theory of, 298

Epidemic disease in Dundalk, 1663
Epidemic diseases, principal, in Ireland, 809
Epidemic diseases in Scotland, 1493
Epidemics in Aberdeen, 1804
Epidemics in schools (Parliamentary question), 736
Epilepsy, causes of sudden death in, 400; diet in, 410; œdema of pia-arachnoid in, 933; causing convulsions, 934; relation of, to left-handedness, 1645; researches in, 1072; surgical treatment of some forms of (Dr. W. Alexander), 932; treatment of, 400, 1305; by fenestration of dura mater, 935
Epinine for ophthalmic use, 1411
Epinine and cocaine hydrochloride, 231
Epithelioma of laryngo-pharynx, 1627
Epithelioma (see Chorion epithelioma); scrotal, radical operation for, lymphatics of scrotum in relation to (Mr. J. Morley), 1545
Epsom College, annual general meeting, 113; extraordinary meeting of governors, 1351, 1498; Founder's day, 389
Equines, sclerostomiasis in, 401
Ergot, physiological standardisation of, 1419
Erratum, 1563, 1780
Erysipelas complicated with meningitis following intranasal operation, recovery (Mr. L. A. Parry), 944; following intranasal operation complicated with meningitis, case of, 827
Esperanto, 1601
Essex, county of, report of school medical officer, 963
Ether anæsthesia by open method, improvements in (Dr. J. Robertson), 1010; inhalation of, pioneer of anæsthesia by, 1701; new frame for administration of, by open method, 302; use of, 1842 and 1911, 1701
Ethics, medical, in Sweden, 245
Ethmoidal, suppuration of, 1180
Ethyl, chloride of, as a general anæsthetic, 57
Eugenic Congress, International (leading article), 1345
Eugenics, First International Congress on, date and place of meeting, 1287; Galton laboratory of, 1033; medical aspect of, 1463, 1464; professorship of, first appointment to, 226; sterilisation from standpoint of, 1702; question in, 328, 472, 546, 722, 852, 915, 968; (Mr. H. H. Ellis), 795; in Belfast, 1522; in Michigan, 1524
Eurich, Dr. F. W., some interesting cases of typhoid fever, 1704
Europe, hospitals of, equipment, 1048
Europeans at Palermo, cholera among, treatment of by injections of hypertonic salines and permanganates, 1403
Evagination of Meckel's diverticulum, 686
Evans, Mr. G. J., and Cole, Mr A. F., case of abdominal streptotrichosis, 1170
Evans, Mr. J. J., discussion on operative treatment of glaucoma, 382
Eve, Sir F., appointment to, 362; case of myeloid sarcoma of the tibia, 1137
Evelina Hospital for Sick Children, information for students, 600
Everington, Dr. H. D., and Coleman, Dr. A. L. E. F., chronic obstruction of the bowel in a hydrocephalic imbecile, results at post-mortem examination, 820
Evidence, medical, question of fee in case under Workmen's Compensation Act, 548
Evolution, Convergence in, 1911 (Dr. A. Willey) (review), 160
Ewart, Dr. C. T., amenorrhœal insanity, 1703; question in eugenics, 472, 915
Ewart, Dr. W., discussion on asthma, 368; on diagnosis and treatment of chronic pulmonary affections of children, 445; method for the clinical use of carbonic acid gas, 505; National Insurance Bill, 250, 328
Ewing, Mr. W. T., and Guyer, Mr. R. G., official ointments, 1499
Examination, Treatise on Diagnostic Methods of (Prof. H. Sahli) (review), 762
Examinations, medical observations upon 17,000, conducted chiefly for public service, 523; one-portal system (leading article), 1145
Examining Board in England by the Royal Colleges of Physicians of London and Surgeons of England, pass lists, 196, 412, 1048, 1108
Excessive sickness clause of National Insurance Bill, 1448
Exercise in diabetes mellitus, 1252
Exercises in Treatment of Lateral Curvature of Spine and Flat-foot (Dr. J. S. K. Smith) (review), 1491
Exeter, Children's Home at, 1071; city of, report of school medical officer, 848
Exeter City Asylum, 721
Exeter Sanatorium, enlargement of, 970
Exhibitions: British Medical Associations, 336, 388, 461; Fractures, 1233; Health Conference and Exhibition, 1376; International Hygiene Exhibition at Dresden, 243, 547, 712, 861, 1162; (British Section opened) 111; London Medical, 1026; Medical Mission Exhibition, 1818; Missionary Exhibition, 926; Public Health Exhibit at Toronto Exhibition, 973; Pure Foods Exhibition, New York, 1168; Smoke Abatement Exhibition, 1519; Tuberculosis Exhibition, Glasgow, 971; Turin Exhibition, 1308; Health Exhibition, "Ui Breasail," Dublin, 1436
Exmouth, medical charities at, 1354
Exostosis, ivory, of frontal sinus, case of, 1479
Experiments on living animals, 341
Exploratory operation, importance of, 287
Explosion at oil-cake manufactory, 1786
Extraperitoneal compression of common iliac artery for prevention of hæmorrhage in disarticulation of hip, 110
Extra-uterine pregnancy, case of, with remarks upon diagnosis, 1828
Eye, complications of, in case of acute antrum of Highmore, 1075; Diseases of (Dr. J. E. Weekes) (review), 1078; Errors of Accommodation and Refraction of, and their Treatment (Mr. E. Clarke) (review), 1707; Text-book in Form of Clinical Lectures (Lehrbuch Augenheilkunde in der Form klinischer Besprechungen) (Dr. P. Römer) (review), 164; melanotic sarcoma of, removed by operation ten years previously, case of melanotic sarcoma of liver, secondary to, 363; Refraction of (Mr. G. Hartridge) (review), 164
Eye and dental clinics for school children in New York, 1375
Eye, face, and tongue, sense of pressure in, 1419
Eyes, effect of drought on, 1047
Eyes, glass, seizure of, in America, 1666
Eyesight, defective, remarkable statistics regarding, 1814
Eyesight of Samuel Pepys, 124

F

Face as index to character, 3
Face and tongue, pressure-pain sensibility in, 1738
Face, eye, and tongue, sense of pressure in, 1419
Face, pharynx, larynx, and tongue, unilateral paralysis affecting, 1702
Factories, conditions in, of New York State, 1239; Indian, accidents in, 976
Factory Girls' Country Holiday Fund, 274, 740
Factory legislation, further, needed for New York State, 1807
Faculty of Medicine, Paris, disturbances at, 1523
Fæces, researches on, in epileptics, 1074
Faith Healing, Faith, Medicine, and the Mind, 1911 (Dr. C. Reinhardt) (review), 23

Medical Registration Act of Bombay, 1375
Medical School of South Africa, appointments, 481
Medical schools in United States, 1048; of London, opening of, for Winter Session 1911-12, 716; of Sweden, 244; and hospitals in Germany, connexion between, 1352
Medical Service, annual, in Liverpool, 1235; naval, improvements in (leading article), 774; under the state, 376; public need for unification in, 457; shortage in, 1427
Medical Sickness and Accident Society, 132, 1307, 1597, 1888; annual meeting, 981
Medical Surgical Aid Society, 1634

MEDICAL SOCIETIES.

ÆSCULAPIAN SOCIETY.—Vagaries in fashions of treatment during the past quarter of a century, 1077
BATH CLINICAL SOCIETY.—Exhibition of cases, 1139—Carcinoma of the small intestine, 1408
BRADFORD MEDICO-CHIRURGICAL SOCIETY.—Some interesting cases of typhoid fever; Some common fallacies of medical logic, 1704
BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.—Exhibition of cases and specimens, 1138, 1408, 1485—Social legislation and the medical profession; Erysipelas following an intranasal operation; exhibition of cases, 827—Exhibition of cases, 1705
BRISTOL MEDICO-CHIRURGICAL SOCIETY.—Myatonia congenita; Tea poisoning; Exhibition of cases, 1407
CLINICAL SOCIETY OF MANCHESTER.—Exhibition of cases, 1558
DEVON AND EXETER MEDICO-CHIRURGICAL SOCIETY.—Eclampsia, 1200—Pulmonary gangrene with operation and recovery; Mycotic infection, 1483
EDINBURGH MEDICO-CHIRURGICAL SOCIETY.—Exhibition of cases; Lymphadenoma; Part played by the upper air passages as avenues of general infection, 156—President's address; Exhibition of cases; tabes, with severe gastric crises treated by resection of the nerve-roots, 1336, 1337—Position of stomach as a guide to pyloric or duodenal difficulty; Vaccine and therapy, 1625
EDINBURGH OBSTETRICAL SOCIETY.—Chylous mesenteric cyst simulating pelvic tumour; Repeated Cæsarean section for contracted pelvis, 96—Contribution to the theory of enzygotic (mono-chorionic) twins; Mongolism; Two rare pelvic tumours, 298—Valedictory address, 1484
GLASGOW MEDICO-CHIRURGICAL SOCIETY.—Primary vesical tuberculosis, 1407—Exhibition of cases; Spinal affections following enteric fever; Dislocation of metatarsus at Lisfranc joint; Anatomical method of enlarging "gridiron" incision, 1629
GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—Acidity in milk; Substitute feeding of infants, 1408—Cancer of the uterus; three cases of malignant disease of the uterus treated by vaginal hysterectomy, 1568
GLASGOW AND NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETIES.—Operative treatment of "procidentia," 158
HARVEIAN SOCIETY OF LONDON.—Discussion on the diagnosis and treatment of tuberculosis of the urinary tract, 1405—Exhibition of cases, 1139—Some early signs and symptoms in nervous disease; Syphilitic affections of bones in childhood, 1625—Some surgical cases illustrating the diagnostic value of X rays; chloroformisation of patients sitting in the upright position, 1774
HUNTERIAN SOCIETY.—Exhibition of specimens, 1775
LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—Some aspects of high blood pressure; Exhibition of cases and specimens, 1482—Two new major operations; Exhibition of cases and specimens, 1270—Treatment of uterine displacements; Exhibition of cases and specimens, 1628
LIVERPOOL MEDICAL INSTITUTION.—President's address; Abscess of the brain; Wassermann test for syphilis, 1336—Albumin reaction in tuberculous sputum; Orthopædic surgery; New cell proliferant, 1485—Exhibition of cases and specimens; Influence of the adrenal, pineal, and pituitary glands upon primary and secondary sex characters; Intestinal concretions; Wounds of the thoracic duct; Sacrococcygeal meningocele with imperforate anus; Nerve anastomosis infantile paralysis, 1555—Exhibition of cases; Value of pneumococcal vaccine in the treatment of acute lobar pneumonia, 1774
MANCHESTER MEDICAL SOCIETY.—Auricular fibrillation; Headache in children; Salvarsan, 1406—Nomenclature of chronic arthritic diseases, 1775
MEDICAL SOCIETY OF LONDON.—Differential diagnosis of syphilis and parasyphilis of the nervous system, 1480—Society and the general practitioner, 1076—Exhibition of cases, 1553—Some remarks on 400 operations involving the peritoneum, 1773
MEDICO-CHIRURGICAL SOCIETY OF GLASGOW.—Exhibition of case; Vaccine treatment of gonococcal arthritis, 1271—Presidential address, 1138
MEDICO-LEGAL SOCIETY.—Annual general meeting, 61—Transactions of, for Year 1910-11 (review), 1632
MEDICO-PSYCHOLOGICAL ASSOCIATION.—Diploma in Psychological Medicine; Treatment of insanity, 1272—Annual meeting, date and programme, 60—Sterilisation from the eugenic standpoint, 1702—Amenorrhœal insanity (joint meeting with Obstetrical and Gynæcological Section of Royal Society of Medicine), 1703
NEW LONDON DERMATOLOGICAL SOCIETY.—Exhibition of cases, 226, 1201, 1487
NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—Description of cases, 1271—Exhibition of cases and specimens; Acute inversion of uterus; Early rising after cœliotomy, 1555
NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—Recent views upon neurasthenia, hysteria, and allied neuroses, 1338—Treatment of bacterial disease by vaccines, 1486—Exhibition of cases and specimens, 1557—Alcohol as a drug, 1704
OPHTHALMOLOGICAL SOCIETY.—Dust-like opacities; Ocular conditions found in Mongolian idiots; Exhibition of cases and specimens, 1404—Presidential address; Hereditary cataract; Hereditary night-blindness; Exhibition of cases and specimens, 1199
OXFORD MEDICAL SOCIETY.—Attack of unconsciousness in an Indian; Double proptosis; Crossed paralysis; Eclampsia, 1201—Safe method of admistration of chloroform, 1705—Fate of appendix after abscess formation, 1705
ROYAL ACADEMY OF MEDICINE IN IRELAND.—*Section of Medicine*. Triad of clinical records; Gangrenous dermatitis, 1557—*Section of Surgery:* Fatal case following injection of "606"; Spinal anæsthesia in prostatectomy, 1556—*Section of Obstetrics:* Pregnant myomatous uterus; Cæsarean section, 1627
ROYAL SOCIETY OF MEDICINE.—*Section of Anæsthetics:* Deaths under anæsthesia; Acute post-anæsthetic bronchitis and (?) pleurisy; Persistent vomiting during induction of anæsthesia for extraction of teeth; Oral airway in anæsthesia, 1335—Methyl and acetone chloroform, 1701—*Section of Balneology and Climatology:* Samuel Hyde memorial lectures on outlines of medical hydrology, 6—Presidential address; British health resorts, 1335—*Section for the Study of Disease in Children:* Exhibition of cases and specimens; Portals of infection in tuberculosis, 225—Exhibition of cases and specimens; Night blindness, 1335—Exhibition of cases and specimens; Purpura in acute infective diarrhœa in infants; Congenital flexion of joints of the fingers, 1552—*Clinical Section:* Exhibition of cases, 1137, 1698, 1478—Treatment of cholera, 1403—*Laryngological Section:* Exhibition of cases, 1403—Exhibition of cases and specimens, 1701—*Medical Section:* Slight strokes, 1198—Influence of certain accessory food-stuffs (tea, coffee, &c.) on gastric secretion; Association of hysteria with malingering; 1551—*Obstetrical and Gynæcological Section:* Large fibro-cystic tumour of the perineum; Specimens, 1075—Cystic degeneration of the chorion; Exhibition of specimens, 1772—*Pathological Section:* President's opening remarks; Experimental production of appendicitis by intravenous inoculations of diplococcus; Sarcoma-producing mouse carcinoma; Muci-carmine staining method; Carcinoma of the uterus in a rabbit, 1199—Arterio-myomatosis, 1552—*Surgical Section:* Caries of frontal bone, 1478; Division of posterior spinal nerve-roots for pain, visceral crises, &c., 94—Intestinal obstruction following ovariotomy; Radical cure of hernia in infants; Treatment of club-foot, 1771
SCOTTISH OTOLOGICAL AND LARYNGOLOGICAL SOCIETY.—Exhibition of cases and specimens, 1627, 1628
SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—Cases illustrating methods of mechanical treatment, 1338—Simple melancholia, 1486
SOCIETY OF MEDICAL OFFICERS OF HEALTH.—National Insurance Bill, 1406—Presidential address, 1138—Notification of Births Act (1907), 1705
UNITED SERVICES MEDICAL SOCIETY.—Presidential address; The new bullets, 1137—Supply of water in the field, 97
WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—Exhibition of cases, 1338—Gastro enterostomy for gastric and duodenal ulcer, 96—Induction of president; Future of surgery, 1076—Unrecognised diphtheria, 1629
WIGAN MEDICAL SOCIETY.—Perforated duodenal ulcer and mistaken diagnosis of lead poisoning, 1775

Medical Societies of Sweden, 244
Medical Society of London and general practitioners, 1076
Medical specialists in ancient Rome, 137
Medical staffs, honorary, representation upon boards of management of voluntary hospitals (Dr. E. S. Reynolds), 1028
Medical stores in Russian army, 1228
Medical students, registration of, discussed at General Medical Council, 1638; German, freedom of, 1351; relations of State to, 1352
Medical substitutes, fees of, 1237
Medical training, cost of, in Norway, 36; Chinese, new scheme, 483; elementary, for missionaries, 810
Medical treatment of the poor, 376
Medical unionism, New South Wales, 483
Medical witness, claim of privilege by, allowed, 1663
Medical workers, service for, in Brighton, 1262
Medicine, address in (Canadian Medical Association), 126; on mistakes (Dr. B. Bramwell), 281; ancient allusions to, by classical writers, 702; article on, in "Encyclopædia Britannica," 1035, 1355, 1504; Biblical-Talmudic, Contributions to History of Healing Art and to Culture in General (Biblisch-talmudische Medizin: Beiträge zur Geschichte der Heilkunde und der Kultur überhaupt (Dr. J. Preuss) (review), 161; condition of, in Scandinavia, 244; contributions to science of, in Norway, 36; economic, and Governments, 106; Essays and Clinical Studies in (Dr. F. G. Crookshank) (review), 1273; evolution of, in Sweden, 244; French Congress of, 1303; Handbook of Medical Treatment of, 1911 (Dr. J. Burnet) (review), 229; History of (Geschichte der Medizin) (Dr. M. Neuburger) (review), 436; illegal practice of, in France, 1243; Internal (Lehrbuch der Therapie innerer Krankheiten, I. Band (edited by Dr. P. Krause and Dr. P. Garré), 1911 (review), 1339; Ninth Australasian Congress on, 1440; practical studies in, preliminary course for, in France, 128; psychological diploma in, 1272; research in (Sir H. T. Butlin), 987; Seventeenth International Congress of, London, 1913, meeting of organising committee, 320; in Norway, 36; in Scandinavia (Denmark), 36, 114
Medicine and Biology, Radium in (Dr. E. R. London) (review), 162
Medicine and chemistry, meeting point of, 1085

MEDICINE AND THE LAW.—Absence of a house surgeon from an inquest, 1224—Action arising out of sale of medical practice, 1634—Action for libel by a medical man against another

(Pocock *v.* Hornibrook), 184—Action for negligence against Sherborne School, 184—Action for the recovery of fees, 1223—Case of Miss Holder, 1356—Danger of dogs not under proper control, 1033—Death from drinking carbolic acid, 1144—Druggist and a case of poisoning, 1034—Exhibition noises and neighbouring residents, 1505—Hebert *v.* Royal Society of Medicine, 1724—Hospital witnesses and fees at inquests, 1033—House surgeon's claim under the Workmen's Compensation Act, 1223—Juries and sympathy in cases of infanticide, 1223—Keeping a lunatic in an unlicensed house, 116—Medical examination under the Workmen's Compensation Act, 1505—Medical man and justifiable use of force, 1357—Medical men and the Midwives Act, 1356—Murder committed by a person under the influence of mental distress, 116—New regulations affecting the sale of some poisons, 1144—Old age pensions and starvation, 1357—Petty frauds upon medical practitioners, 1724—Proposed Weir Hospital at Streatham, 116—Rex *v.* George Douglas Hay; Guilty but insane, 184—Rink and its neighbours, 1724—The carrying of pistols, 1144—Trials for infanticide, 1356—Two kindred bogus claims for accidents, 1724

Medicine, practice of, in British Columbia, 1736
Medicine and the State, 279
Medicine and Surgery, Quinquennium of, 1906-10, edited by Dr. J. W. Ballantyne (review), 1339
Medicines, proposed restrictions on journalistic puffing of, 479; secret and proprietary, 462
Medico-Legal Society, annual dinner, 308
Medico-military service of Italy, 1304
Medico-Psychological Association, 940; of Great Britain and Ireland, dinner of, 399; meeting of, 261, 399
Mediterranean fever, influence of, on fœtus in utero (Dr. R. Samut), 878
Meisser, Prof., accident to, 1597
Melancholia, simple, 1486
Melbourne, health of, 863
Melbourne Hospital, new buildings for, 1667
Mellanby, Dr. E., a short chemical study of a case of cyclic vomiting, with some remarks on creatinuria and acidosis, 8
Melland, Dr. C. H., discussion on obscure cases of fever without physical signs, 441; on tuberculous peritonitis, 372; and Bishop, Mr. E. S., partial gastrectomy for cancer of pyloric end of stomach, 1558
Melville, Lieut.-Col. C. H., discussion on relatively low protein diet, 386; physiology of the march, 10 6; and White, Dr. D., venereal disease, its present, past, and future, 1615, 1692; (leading article), 1715
Melville-Davison, Dr. W., Some New and Interesting Points in Ships' Hygiene, 1911 (review), 894
Me-malto wine, 692
Memorial hospital, proposed, to the late Sir Charles Dilke, 970, 1370
Memorial meetings for departed medical men, 778
Memorial window at Bristol Royal Infirmary, 53
Men and animals, action of tropical sun on, 777
Men, summer clothing for, 392
Meningeal symptoms, onset of typhoid fever by, 110
Meningitis complicating case of erysipelas following intranasal operation, 827; cerebro-spinal, 1650; cerebro-spinal, and acute poliomyelitis, 1719, 1782; cerebro-spinial case of, in Bristol, 857; cerebro-spinal (Parliamentary question), 1598; outbreak of, in County Roscommon, 1302; and acute poliomyelitis (leading article), 896; and acute poliomyelitis in Devon and Cornwall, 843; and poliomyelitis, notification of, in Bristol, 1097; spotted fever, in West of England, 549, 725; erysipelas complicated with, following intranasal operation, recovery (Mr. L. A. Parry), 944; following measles (Dr. C. A. Basker), 499
Meningocele, sacrococcygeal, associated with imperforate anus, 1565
Meningo-encephalocele, ruptured, case of operation for, 1198
Mental affections, trauma in relation to, 450
Mental disease, need for chemistry in investigation of, 515
Mental diseases, clinic of, 481; use of salvarsan in, 1646
Mental disorder, psychotherapy in, 399
Mental disorders, leucocytosis in, 932
Mental distress, murder committed by person under influence of, 116
Mental expression, body sole agent of, 2
Mental Hospital of the City of Cardiff (report for the year 1910), 1507
Mental Mechanisms (Nervous and Mental Disease Monograph Series, No. 8) (Dr. W. A. White) (review), 831
Mental reaction, classification of temperaments based on, 3
Mentone, refuse of, thrown into ravines, 50
Mercer's Hospital, Dublin, information for students, 626
Merchant service, prevalence of pulmonary tuberculosis in (Dr. M. MacKinnon), 885
Merchant ships, medical equipment for, 1148, 1231
Mercier, Dr. C. A., Crime and Insanity, 1911 (review), 952
Merck's Annual Report, 1243
Mercurial poisoning, acute, fatal case of (Mr. A. W. Burton), 297
Mercury, diet during treatment with, 137; iodide of potassium and "606" compared experimentally as antisyphilitics (Dr. J. McIntosh and Dr. P. Fildes), 940; and salvarsan ("606") in treatment of syphilis, 121, 122, 188, 253, 326, 473, 547, 853; in treatment of syphilis, 1386
Mergentheim tablets, 1143
Mesentery, cyst of, chylous, simulating pelvic tumour, 96; enlarged tuberculous glands in, 508; fibromatous tumours of, 508
Mesopotamia, cholera in, 854
Metabolism in insane, 515; in insanity, 932
Metastasis, 1536
Metatarsal bone, lead bullet removed from, after 23 years (Mr. J. B. Christopherson), 1544
Metatarsus, dislocation of, at Lisfranc joint, 1629
Meteorological daily readings, 67, 138, 275, 344, 421, 491, 559, 665, 741, 807, 869, 929, 985, 1052, 1115, 1176, 1245, 1313, 1383, 1455, 1533, 1603, 1673, 1753, 1818
Meteorologists, amateur, weather instruments for, 806
Methylated spirit, drinking of, 478; spontaneous combustion of, 475, 796
Metropolitan Ear, Nose, and Throat Hospital, information for students, 601
Metropolitan Hospital Sunday Fund, 320, 391, 1641, 1881; amounts collected, 24, 115, 174, 245
Mice immunised subcutaneously resistant to implantation of cancer of internal organs (Dr. W. H. Woglom), 92
Michigan, eugenics in, 1524
Micro-organism, hitherto undescribed, causing acute endocarditis (Dr. A. T. Nankivell), 1134
Micro-organisms and Fermentation, 1911 (Dr. A. Jörgensen) (review), 20
Micrococcus melitensis and bacillus typhosus, agglutination of, by normal sera, variability of, and importance of, in laboratory diagnosis (Mr. E. C. R. Fox), 877
Micrology, Animal, Practical Exercises in Microscopical Methods (Prof. M. F. Guyer) (review), 503
Microparasitology, Treatise on (Dr. W. Kolle) (review), 1630
Microscope, resolving power of, 253
Microscopical methods of demonstrating spirochæta pallida, comparative value of, 523
Middlesex, county of, annual report of medical officer of health, 1423
Middlesex Hospital, 1624; annual dinner, 1037; connexion of Prince Francis of Teck with, 996; events in early history of, 994; events in later history of, 995; first lying-in hospital in England, 993; foundation of, 993; historical sketch of (Dr. C. Berkeley), 993; inadequacy of out-patient department, 998; inception of present building, 993; information for students, 577; medical staff of, 997; post of secretary to, 998
Middlesex Hospital Medical School, award of scholarships and prizes, 555, 1173; institution of, 995
Middleton, Dr. G. S., and Teacher, Dr. J. H., injury to the spine due to muscular effort, 958
Midland Counties Asylum, change of name, 1164
Midland Ophthalmological Society, 1526
Midwifery, Operative (Dr. J. M. Kerr) (review), 763
Midwives, inspection of, in Cornwall, 477; pupil, instruction for, 1381; refusal to appoint, by Cookstown board of guardians, 1166; untrained, cause of blindness in babies, 258; and National Insurance Bill, 1369; Act (1902), 132; medical men and, 1356
Miers, Dr. H. A., introductory address on lucidity, delivered at St. George's Hospital Medical School on Oct. 2nd, 1911, 990
Mikhailoff, Prof. M. N. A., syphilis of the bladder and of the upper urinary passages, 1151
Miles, Mr. W. E., treatment of carcinoma of rectum, 1775
"Military surgeon, the," 1797
Military Surgeon (review), 1041
Military training, recent, on Salisbury Plain 1365
Milk, care of, in Montreal, 480; condensed, crusade against, 137; conveyance of infectious diseases by, 1101; development of acidity in, relation of, to time and temperature, 1408; fine for watering of, 1241; lack of, in Paris, 1100; preserved (Parliamentary question), 736; Pure, Production of, Methods Employed at Infants Hospital Farm (Dr. R. Vincent) (review), 689; Pure, Conference for Provision of, for Victoria, 1667; sale of (Parliamentary question), 134, 1309
Milk Commission, Ireland, 1742
Milk and Dairies Bill (Parliamentary question), 1308; and tuberculosis, 1236; (Parliamentary question), 341, 416; depot for Cardiff, 1520
Milk feeding, in children after first year, disturbances arising from, 445
"Milk food," 692
Milk, foreign, and contagious diseases (Parliamentary question), 1598
Milk legislation (Parliamentary question), 199
Milk purveyors, registration of, 728
Milk stations (city owned) of New York, 730; effect of, upon infant mortality in Montreal, 480; of New York milk committee to be closed, 1375
Milk-supply Commission, Irish, 1592
Milk-supply, problem of, in New York, 1239
Milk-supply in Ireland, 1436
Milk of thyroidless goats in treatment of Graves's disease (Mr. W. Edmunds), 1618
Milk vendors, heavy fines upon, 259
Milks, condensed, in infant dietary, 966, 967; (leading article), 833
Mill, Dr. H. R., British Rainfall, 1910 (review), 894
Mill-road Infirmary, Liverpool, new laboratories at, 257
Millard, Dr. C. K., discussion on tuberculosis dispensaries, 384; vaccination in regard to life assurance, 252
Millardet, M., pleural effusion with rigidity of the pleura and mediastinitis, 1025
Miller, Dr. H. C., discussion on treatment of morphinism, 506
Miller, Dr. R. H., case of hæmochromatosis with diabetes, 1479; Medical Diseases of Children, 1911 (review), 827
Miller, Dr. R. S., National Insurance Bill, 1512
Miller General Hospital, 334
Milligan, Dr. W., and Wingrave, Dr. W., Practical Handbook on Diseases of the Ear, for Senior Students and Practitioners, 1911 (review), 1408
Millington, Dr. W., obituary, 1594
Mills, Mr. G. P., action of radium on healthy tissues, 521
Milne, Dr. R., measles, its treatment and prevention, 511; treatment of scarlet fever by his method, 971
Milton, Mr. F., the National Insurance Bill, 46
Mind, qualities of, relations of uniformity of structure to, 3; Unsoundness of (Dr. T. S. Clouston) (review), 226
Miners, health of, in Queensland, 131
Miner's phthisis, 1538
Mines, demonstration of various forms of rescue apparatus employed in, 509
Minot, Prof. C. S., Laboratory Text-book of Embryology, second edition, 1911 (review), 1015
Miscellany of Verse (Mr. J. J. Mooney) (review), 1341
Missionaries, elementary medical training for, 810
Missionary exhibition, 926
Mistakes, address in medicine on (Dr. B. Bramwell), 281
Mitchell, Dr. A. P., scholarship awarded to, 414
Mitchell, Mr. C. A., Science and the Criminal, 1911 (review), 22
Mitchell, Mr. L. J. C., use of carbon-dioxide snow in ophthalmic work, 520
Mitchell Banks memorial lecture, 1435
Mitra, Mr. S. M., Life and Letters of Sir John Hall, M.D., K.C.B., 1911 (review), 768
Mitral stenosis, paralysis of left recurrent laryngeal nerve in, 468
Mocquot, M. P., and Delbet, M. P., Affections Chirurgicales des Artères (Surgical Affections of the Arteries) Nouveau Traité de Chirurgie (New Treatise on Surgery), 1911 (review), 1204
Molony, Dr. B. J. de W., and Rolleston, Dr. H. D., purpura in acute infective diarrhœa in infants, 1552
Monaco, principality of, refuse destructor in, 50
Monaghan and Cavan asylum board, 551
Mongolism, 298
Monism and dualism, battle of (leading article), 1209

Monkey, experimental measles in, 699, 1348
Monmouthshire Asylum at Abergavenny, annual report for year 1910, 366
Monod, Dr. G., British health resorts for foreign invalids, 969; remarks on British health resorts, 1336
Monod, M., obituary, 1438
Monsoon, failure of, in India, 924
Montenegro, cholera in, 539, 864
Montreal, antivaccination movement in, 564; care of milk in, 480; cocaine in, 923; contagious diseases of, in 1910, 923; filtration plant for, 730; infant mortality, 1593; infant mortality in, effect of milk stations upon, 480; insanitary conditions in, 923; meeting of Canadian Medical Association in, 125; opening of new medical buildings of McGill University, 256; vital statistics of, 923
Montrose Asylum, annual meeting, 54
Montrose Royal Asylum, proposed reduction of attendants' hours, 858
Monument, new Greek, to Asklepios and Hygieia, 1243
Moon, Dr. R. O., a case of tricuspid regurgitation, 1477
Mooney, Mr. J. J., Miscellany of Verse, 1911 (review), 1341
Moor, Sir J. W., suggested diagnosis of malignant scarlatina anginosa, 256
Moore, Prof. B., relation of the organic phosphorus content of various diets to diseases of nutrition, particularly beri-beri, 1230; strike and the death rate in Liverpool, 1297, 1431
Moore, Dr. F. C., and Allanson, Dr. H. E., influence of certain accessory food-stuffs on gastric secretion, 1551
Moore, Mr. H., case of early general paralysis of the insane treated by "606" with fatal results, 1556
Moore, Sir J., triad of clinical records, 1557
Moore, Dr. N., remarks at distribution of prizes at Epsom College, 389
Moore, Mr. S. W., medical equipment for merchant ships, 1231
Moorhead, Dr. T. G., discussion on fatal result after treatment by "606," 1556
Morin, Dr. E., Guide Pratique de l'Infirmière-Hospitalière et de l'Infirmier-Brancardier: Bandages Usuels—Premiers soins d'Urgence—Relèvement et Transport des Blessés, 1911 (review), 504
Morison, Mr. A. E., operative treatment of retroversion and prolapse of the uterus, 821
Morison, Mr. J. Rutherford, opening of discussion on treatment of general septic peritonitis, 369
Morison, Prof. R., year's work in abdominal and pelvic surgery in the Royal Victoria Infirmary, Newcastle-upon-Tyne, and in a private hospital during 1910, 1683
Moritz, Dr. S., discussion on treatment of laryngeal tuberculosis, 375
Morley, Mr. J., lymphatics of the scrotum in relation to the radical operation for scrotal epithelioma, 1545
Morning "nips," 483
Morningfield Hospital, Aberdeen, annual general meeting, 54
Morphine, supposed loss of, in preparation of tincture of opium, 319
Morphinism, treatment of, 506
Morphœa, linear, 1485
Morris, Sir H., Bart., presidential address at annual meeting of Royal Society of Medicine, 180; remarks at annual distribution of prizes, Epsom College, 389; at annual meeting of Imperial Cancer Research Fund, 318
Morris, Sir M., discussion on vascular disorders of skin, and their relation to other morbid states, 371; Diseases of the Skin, an Outline of the Principles and Practice of Dermatology, 1911 (review), 1709
